## DESCRIPTION

The Si9913 is a dual MOSFET high-speed driver with break-before-make. It is designed to operate in high frequency dc-dc switchmode power supplies. The high-side driver is bootstrapped to handle the high voltage slew rate associated with "floating" high-side gate drivers. Each driver is capable of switching a 3000-pF load with 60-ns propagation delay and 25-ns transition time. The Si9913 comes with internal break-before-make feature to prevent shoot-through current in the external MOSFETs. A synchronous enable pin is used to

enable the low-side driver. When disabled, the OUT<sub>L</sub> is logic low.

The Si9913 is available in an 8-pin SOIC package for operation over the industrial operation range (-40°C to 85°C).

## THEORY OF OPERATION

### Break-Before-Make Function

The Si9913 has an internal break-before-make function to ensure that both high-side and low-side MOSFETs are not turned on at the same time. The high-side drive ( $OUT_H$ ) will not turn on until the low-side gate drive voltage (measured at the  $OUT_L$  pin) is less than  $V_{BBM}$ , thus ensuring that the low-side MOSFET is turned off. The low-side drive ( $OUT_L$ ) will not turn on until the voltage at the MOSFET half-bridge output (measured at the  $V_S$  pin) is less than  $V_{BBM}$ , thus ensuring that the high-side MOSFET is turned off.

### Under Voltage Lockout Function

The Si9913 has an internal under-voltage lockout feature to prevent driving the MOSFET gates when the supply voltage (at  $V_{DD}$ ) is less than the under-voltage lockout specification ( $V_{UVL}$ ). This prevents the output MOSFETs from being turned on without sufficient gate voltage to ensure they are fully on. There is hysteresis included in this feature to prevent lockout from cycling on and off.
