

OVERVIEW

The SM8146AD1 is a dedicated EL (Electro Luminescence) driver IC, capable of driving EL sheet up to 30cm² in size. The EL drive circuit uses a technique that generates smooth sine wave EL drive waveforms without an output resistor, which has the advantage of preventing EL sheet audible noise, eliminating the need for additional peripheral components and a corresponding drop in power efficiency. Also, the EL drive voltage is constant-voltage controlled and is unaffected by supply voltage fluctuations, so that there are no EL brightness variations due to supply voltage changes. A dimming function is available under direct control from a microcontroller. The logic HIGH-level input voltage range (ENA, DIM pins) starts at 1.4V, allowing the device to be driven directly without external transistors from a Li-ion battery.

FEATURES

- Sine wave EL drive waveforms for low audible noise
- Constant EL drive voltage independent of supply voltage fluctuations
- Separate coil and EL drive frequency adjustment
- Enable function (ENA pin)
- Dimming function (DIM pin)
- Direct control capability using 1.8V system CPU (ENA, DIM pins)
V_{IH} = 1.4V (min, V_{DD} = 2.5 to 5.5V)
- 2.5 to 5.5V supply voltage range
- 170Vp-p (typ) maximum EL drive voltage
- 250Hz (typ) EL drive frequency (R_{OCE} = 200kΩ)
- 0.5mA (typ) operating current
- 1.0μA (max) standby current
- 220μH (typ) recommended inductance
- Package: 10-pin SON

APPLICATIONS

- Cellular phone
- Portable audio equipment
- Handy terminal
- Other portable application

Signal input time ²	DIM	t_{DIMH}	DIM input signal HIGH-level pulsewidth minimum	3.0			μs
		t_{DIML}	DIM input signal LOW-level pulsewidth minimum	3.0			μs
Operating current	VDD	I_{DD1}	Excluding coil current		0.5	1.0	mA
Standby current	VDD	I_{STB}	ENA = LOW		0.01	1.0	μA

1. t_{ENA} is the rating between the following levels.

2. Design guarantee value

OPERATIONAL DESCRIPTION

EL Sheet

■ EL Emission Condition

An AC (30Hz to several kHz) high voltage (60Vp-p to several hundred Vp-p) is required for EL emission. The SM8146AD1 supports an EL drive frequency range of 31Hz to 1500Hz and an EL drive voltage range of 86Vp-p to 170Vp-p.

■ EL Life

The EL drive frequency and EL drive voltage have a simultaneous affect on the EL brightness and EL life span. The EL life decreases when the EL brightness is high, so an optimized value should be selected for the EL sheet used. The EL life also has an effect on the EL drive voltage waveform. The SM8146AD1 EL drive voltage waveform is a sine wave with small high-harmonic components which helps to extend EL life.

■ EL Audible Noise

The EL sheet has a piezoelectric characteristic that generates audible noise when excited by the applied AC high voltage. The SM8146AD1 EL drive voltage waveform is a sine wave with small high-harmonic components which helps to reduce EL audible noise. The EL drive waveform sine wave, generated by the EL drive circuit, does not require an output resistor. Consequently, peripheral components and a corresponding drop in power efficiency can be avoided.

■ EL Drive Voltage (Constant-Voltage Control and Overvoltage Protection)

The SM8146AD1 uses constant-voltage control where the EL drive voltage is set to 7 stabilized voltage amplitude levels determined by the IC internal circuitry. The EL drive voltage amplitude is initially set to the default value of 85V, and then changes in sync with the falling edge of each DIM input pulse in the continuous sequence 85V → 78V → 71V → 64V → 57V → 50V → 43V → 0V (OFF) → 85V. The EL drive voltage constant-voltage control not only eliminates EL brightness variations due to supply voltage fluctuations, but also functions as overvoltage protection when the EL load is removed.

Interface

The SM8146AD1 uses an interface comprised by the ENA and DIM input pins. The ENA and DIM pins have a HIGH-level input voltage range of 1.4V to VDD + 0.3V, enabling direct control from a 1.8V system microcontroller without the need for a voltage converter. Pull-down resistances are built-in.

■ ENA Pin

The ENA pin functions as the IC ON/OFF control. The device is enabled when ENA is HIGH, and disabled when ENA is LOW.

■ DIM Pin

The DIM pin functions as the EL brightness adjustment (dimming) control. The EL drive voltage amplitude reduces in sync with the falling edge of each DIM input pulse in the continuous sequence 85V → 78V → 71V → 64V → 57V → 50V → 43V → 0V (OFF) → 85V. The DIM pin should be connected to GND when EL brightness control is not used.

EL Brightness Adjustment

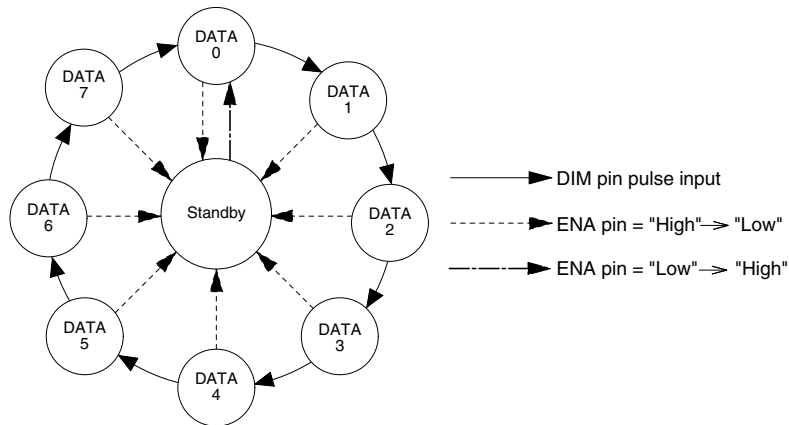

The SM8146AD1 EL brightness can be adjusted using a combination of two methods: (1) EL drive voltage control and (2) EL drive frequency control.

(1) EL Brightness Adjustment using EL Drive Voltage

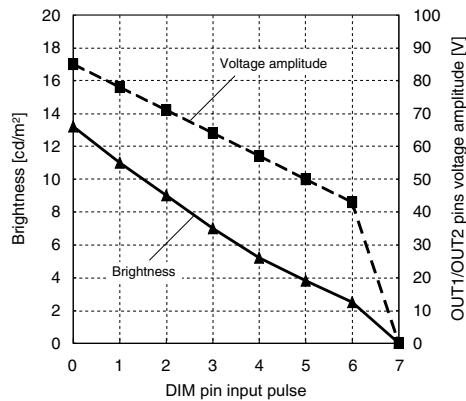

This dimming function changes the EL brightness in response to the EL drive voltage determined by the number of input pulses on the DIM pin. An internal counter is used to count the number of DIM input pulses and the OUT1/OUT2 EL drive voltage amplitude level changes in response, varying the EL brightness. The 3-bit internal counter provides 8-step adjustment (DATA 0 to 7). On the 7th pulse (DATA = 7), the EL sheet is turned OFF. On the 8th pulse (DATA = 0), the voltage is set to the default value (maximum brightness). Since the default value provides the maximum brightness, the DIM pin should be connected to GND when the dimming function is not used.

Table 1. OUT1/OUT2 pins voltage amplitude and DIM pin input pulse count

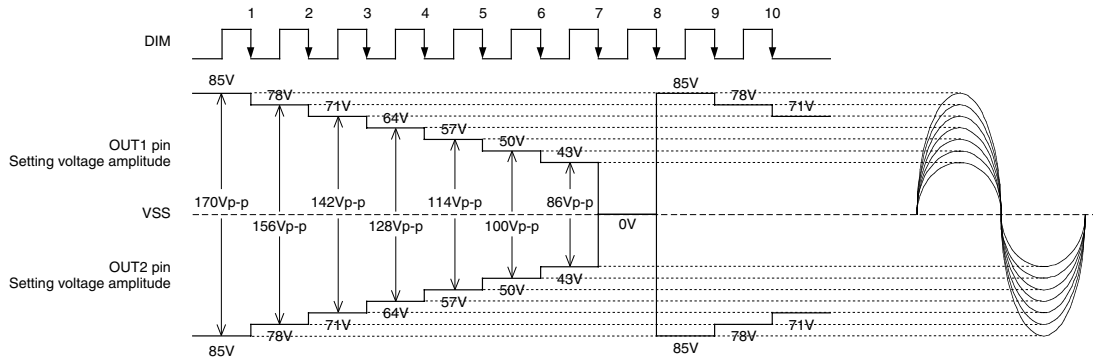

DATA	0	1	2	3	4	5	6	7
DIM pin input pulse count	0	1	2	3	4	5	6	7
	8	9	10	11	12	13	14	15
	16	17	18	19	20	21	22	23
OUT1/OUT2 pins voltage amplitude	85V	78V	71V	64V	57V	50V	43V	0V

Transition diagram of IC internal state by ENA and DIM pins

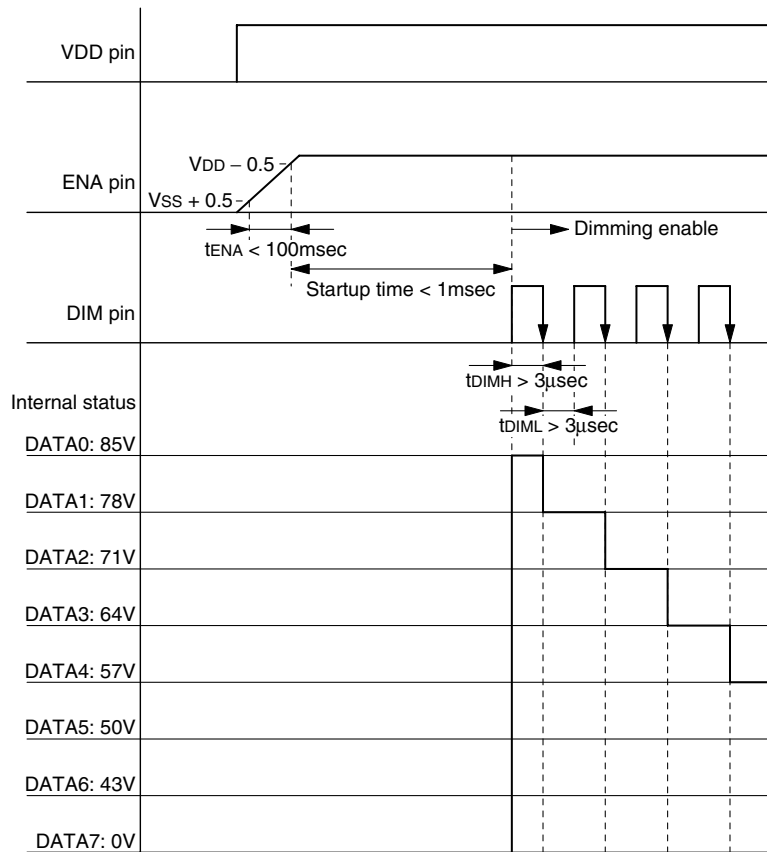

DIM pin input pulse count vs. EL brightness, OUT1/OUT2 pins voltage amplitude

Note: Target values without compensation for voltage accuracy.

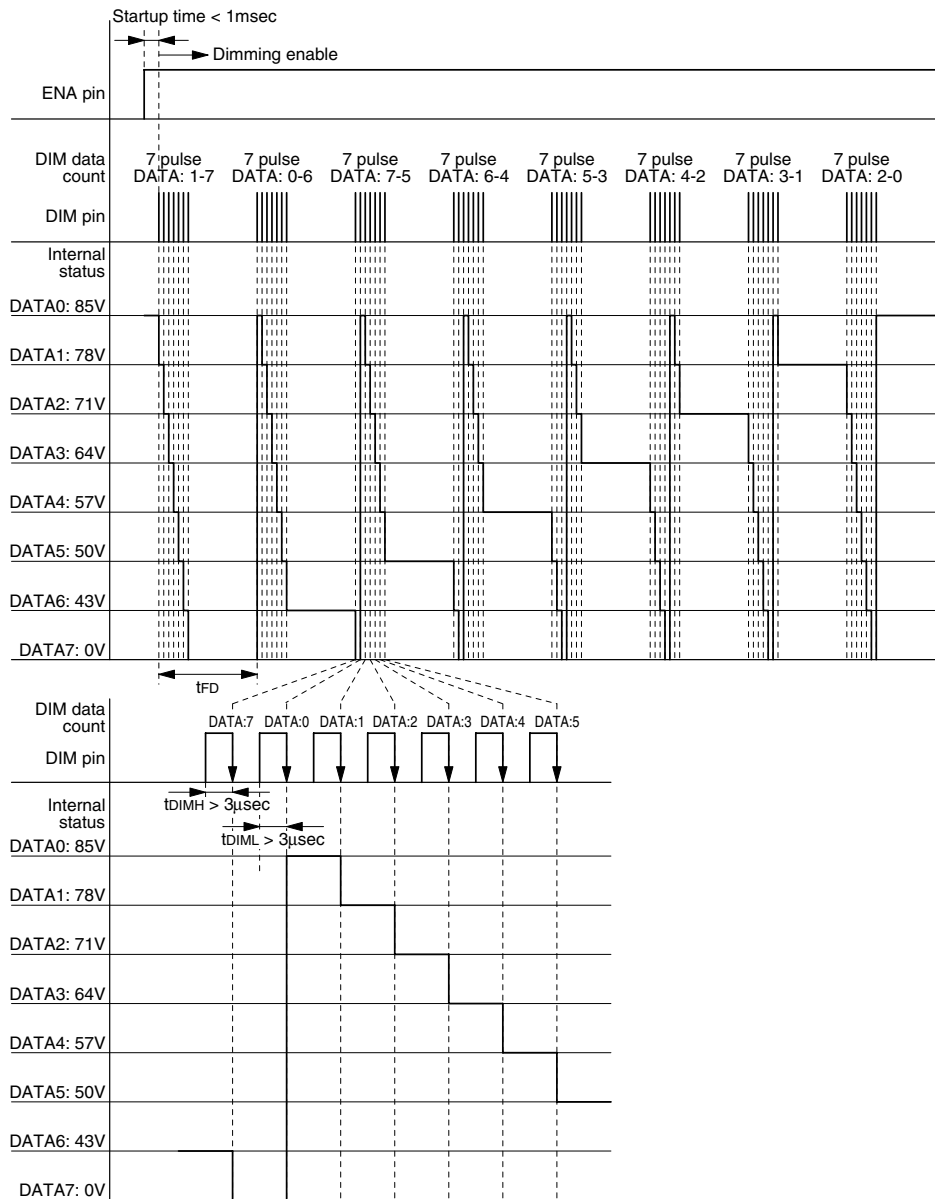

■ Input pulse to DIM pin

The pulse input to DIM pin is allowed after startup time 1msec that is for initializing IC interior with ENA pin at High level. The output voltage is setup at the initial value DATA0: 85V. The pulse input to DIM pin changes the output pin voltage setting, so that the EL brightness can be adjusted.

■ Method to increase EL brightness in steps (Fade-in)

The raise of output voltage in steps by the input pulse to DIM pin increases the EL brightness in steps. The timing chart is shown below. Initially the ENA pin is turned to High level, and then the pulse should be input after startup time 1msec of IC interior. Since the output voltage is setup at the initial value DATA0: 85V, when the seven times in a row of pulse are input to DIM pin, the setup value of output voltage becomes DATA7: 0V which is the first tone of fade-in. When the seven times in a row of pulse are input to DIM pin once again after the time t_{FD} , the setup value of output voltage becomes DATA7: 43V which is the second tone of fade-in. If this operation is repeated six times, the brightness becomes maximum value, thus the fade-in would be realized. The frequency of the pulse which is input to DIM pin should be set up at over several tens of kHz. This frequency is adequately higher than the EL driving frequency in order that the EL brightness does not vary during the continuous pulse input.

Recommended setting value: $t_{FD} = 90\text{msec}$
 $t_{DIMH} = 25\mu\text{sec}$
 $t_{DIML} = 25\mu\text{sec}$

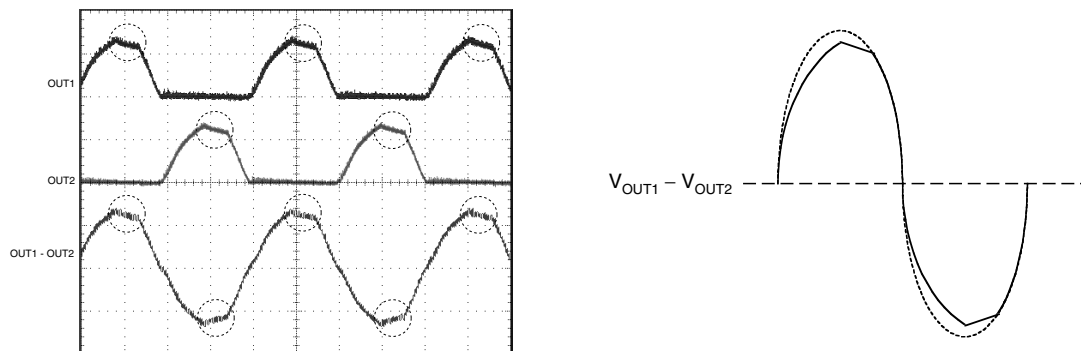

(2) EL Brightness Adjustment using EL Drive Frequency

This dimming function changes the EL brightness in response to the EL drive frequency determined by the value of the resistance of R_{OCE} connected to the OCE pin. This dimming property should only be set when determining the peripheral components. It is not recommended to vary the EL brightness by switching the R_{OCE} resistance.

EL Output Voltage Waveform (Sine Wave) Distortion

Flat regions near the waveform peaks of EL driving voltage are generated in principle of operation. They are not failure and do not affect the brightness and the audible noise.

Depending on conditions, the OUT1/OUT2 output waveform may become distorted as shown by the solid line in the figure above. If the booster circuit drive capability is insufficient, the circuit may not be able to provide the boost required to meet the ideal curve shown by the dotted line in the figure above. This condition can be caused by the inductor supply voltage being too low, the inductance value being too high, the inductor frequency being too high, the EL drive frequency being too high, or the EL surface area being too large.

PERIPHERAL COMPONENT SELECTION

Coil

Booster coil. Where possible, a closed-magnetic circuit type coil should be selected. If the coil inductance is less than 100 μ H, the switching cannot keep pace and the brightness cannot be increased. The coil flowing into the coil is a sawtooth waveform, and care should be taken to ensure the peak current does not exceed the maximum current rating. The coil DC resistive component causes power loss, so a coil with low DC resistive component is advantageous. The recommended inductance is 100 to 470 μ H.

Table 2. Recommended parts list (Attention: R_{OCL} and R_{OCE} should be optimized per inductor.)

Manufacture	Part number	Inductance [μ H]	Dimensions [mm]		
			W	L	T
TAIYO YUDEN	NR4012T221M	220	4.0	4.0	1.2
	NR3010T101M	100	3.0	3.0	1.0
MURATA	LQH3NPN221NG0	220	3.0	3.0	1.0
	LQH3NPN151NG0	150	3.0	3.0	1.0

	1156AS-101M	100	2.85	2.8	1.0
	888FU-221M	220	3.5	3.5	1.7

Diode

Rectifier diode. This diode rectifies the high voltage generated by the coil. The peak reverse voltage exceeds 100V, hence a fast recovery type diode is recommended.

Table 3. Recommended parts list

Manufacture	Part number	Dimensions [mm]		
		W	L	T
TOSHIBA	1SS403	1.7	1.25	0.9
ROHM	RF051VA2S	1.9	1.3	0.6
	RF071M2S	2.6	1.6	0.8

High-voltage capacitor

Smoothing capacitor. This capacitor smooths the high voltage generated by the coil and rectified by the diode. A withstand voltage rating of ≥ 100 V should be selected. Generally, a high-dielectric ceramic capacitor will generate audible noises. The capacitors below are recommended. The recommended value is 0.0022 to 0.0033 μ F (100V).

Table 4. Recommended parts list

Manufacture	Part number	Capacitance [μ F]	Dimensions [mm]		
			W	L	T
MURATA	GRM3192C2A222JA01	0.0022	3.2	1.6	0.85

Panasonic	ECWU1222JX5	0.0022	3.2	1.6	1.1

ELECTROSTATIC BREAKDOWN PROTECTIVE MEASURES (ESD)

Electrostatic breakdown protective measures are required because the keypad comes into direct contact with the human body. The EL sheet surface is coated with an insulating film, but if the electrodes on the EL sheet periphery are exposed, static electricity can flow from these electrodes into the IC and lead to electrostatic breakdown. Accordingly, the EL sheet should be designed so that the electrodes are not exposed, or otherwise covered using insulating tape to provide a similar level of protection.
