**Attention please!**

The information herein is given to describe certain components and shall not be considered as warranted characteristics.

Terms of delivery and rights to technical change reserved.

We hereby disclaim any and all warranties, including but not limited to warranties of non-infringement, regarding circuits, descriptions and charts stated herein.

Infineon Technologies is an approved CECC manufacturer.

**Information**

For further information on technology, delivery terms and conditions and prices please contact your nearest Infineon Technologies Office in Germany or our Infineon Technologies Representatives worldwide (see address list).

**Warnings**

Due to technical requirements components may contain dangerous substances. For information on the types in question please contact your nearest Infineon Technologies Office.

Infineon Technologies Components may only be used in life-support devices or systems with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system, or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body, or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

# 1 Introduction

The C868 is a member of the Infineon Technologies C800 family of 8-bit microcontrollers. It is fully compatible to the standard 8051 microcontroller. Its features include the capture compare unit (CCU6) which is useful in motor control applications, extended power saving provisions, on-chip RAM and RFI related improvements. The C868 has a maximum CPU clock rate of 40MHz. At 40MHz it achieves a 300ns instruction cycle time.

The C868 basically operates with internal program memory only. The C868-1R contains 8Kx8 on-chip ROM of program memory and the C868-1S contains 8Kx8 of on-chip RAM of program memory. Different operating modes are provided to allow flexibility in the access of the different types of memory. An additional RAM, XRAM, is provided for the implementation of in-system programming.

**Figure 1-1** shows the different functional units of the C868 and **Figure 1-2** shows the simplified logic symbol of the C868.

**Figure 1-1 C868 Functional Units**

## 1.1 Summary of Basic Features

Listed below is a summary of the main features of the C868:

- C800 core :
  - Fully compatible to standard 8051 microcontroller
  - Superset of the 8051 architecture with 8 datapointers
- 6.25 - 40 MHz internal system clock (built-in PLL with software configurable divider)
  - external clock of 6.67 - 10.67 MHz
  - 300ns instruction cycle time (@40 MHz system clock)
- 8 Kbyte on-chip Program ROM for C868-1R and 8 KByte on-chip Program RAM for C868-1S
- In-system programming support for programming the XRAM(C868-1R) or XRAM/Program RAM(C868-1S)
  - This feature is realized through 4KB Boot ROM
- 256 byte on-chip RAM
- 256 byte on-chip XRAM
- One 8-bit and one 5 bits general purpose push-pull I/O ports
  - Enhanced sink current of 10 mA on Port 1/3 (total sink current of 46 mA @ 100°C)
- Three 16-bit timers/counters
  - Timer 0 / 1
  - Timer/counter 2 (up/down counter feature)
  - Timer 1 or 2 can be used for serial baudrate generator
- Capture/compare unit (CCU6) for PWM signal generation
  - 3-channel, 16-bit capture/compare unit
  - 1-channel, 16-bit compare unit
- Full duplex serial interface (UART)
- 5 channel 8-bit A/D Converter
- 13 interrupt vectors with 2 priority levels
- Programmable 16-bit Watchdog Timer
- Brown out detection
- Power Saving Modes
  - Slow-down mode
  - Idle mode (can be combined with slow-down mode)
  - Power-down mode with wake up capability through  $\overline{\text{INT0}}$  or RxD pins.
- Individual power-down control for timer/counter 2, capture/compare unit and A/D converter.
- P-DSO-28-1, P-TSSOP-38-1 packages
- Temperature ranges:
  - SAB-C868-1RR,SAB-C868-1SR,SAB-C868-1RG,SAB-C868-1SG  $T_A = 0$  to  $70$  °C
  - SAF-C868-1RR,SAF-C868-1SR,SAF-C868-1RG,SAF-C868-1SG  $T_A = -40$  to  $85$  °C

NC	–	5,7,8,18,19,20,21,22,23,35	–	<b>Not connected</b>
XTAL1	27	29	I	<b>XTAL1</b> Output of the inverting oscillator amplifier.
XTAL2	28	30	O	<b>XTAL2</b> Input to the inverting oscillator amplifier and input to the internal clock generation circuits. To drive the device from an external clock source, XTAL2 should be driven, while XTAL1 is left unconnected.

\*)I=Input  
O=Output

## 2 Fundamental Structure

The C868 is fully compatible to the architecture of the standard 8051 microcontroller family. While maintaining all architectural and operational characteristics of the 8051, the C868 incorporates a CPU with 8 datapointers, a 8-bit A/D converter, a 16-bit capture/compare unit, a 16 bit timer 2 that can be used as baudrate generator, an interrupt structure with 2 priority levels, built-in PLL with a fixed factor of 15 and a variable divider, an XRAM data memory as well as some enhancements in the Fail Save Mechanism Unit. **Figure 2-1** shows a block diagram of the C868.

Figure 2-1 Block Diagram of the C868

## 2.1 CPU

The C868 is efficient both as a controller and as an arithmetic processor. It has extensive facilities for binary and BCD arithmetic and excels in its bit-handling capabilities. Efficient use of program memory results from an instruction set consisting of 44% one-byte, 41% two-byte, and 15% three-byte instructions. With a 10.67 MHz external crystal (giving a 40MHz CPU clock), 58% of the instructions execute in 300 ns.

The CPU (Central Processing Unit) of the C868 consists of the instruction decoder, the arithmetic section and the program control section. Each program instruction is decoded by the instruction decoder. This unit generates the internal signals controlling the functions of the individual units within the CPU. These internal signals have an effect on the source and destination of data transfers and control the ALU processing.

The arithmetic section of the processor performs extensive data manipulation and is comprised of the arithmetic/logic unit (ALU), an A register, B register and PSW register.

The ALU accepts 8-bit data words from one or two sources and generates an 8-bit result under the control of the instruction decoder. The ALU performs the arithmetic operations add, subtract, multiply, divide, increment, decrement, BCD-decimal-add-adjust and compare, and the logic operations AND, OR, Exclusive OR, complement and rotate (right, left or swap nibble (left four)). Also included is a Boolean processor performing the bit operations as set, clear, complement, jump-if-set, jump-if-not-set, jump-if-set-and-clear and move to/from carry. Between any addressable bit (or its complement) and the carry flag, the ALU can perform the bit operations of logical AND or logical OR with the result returned to the carry flag.

The program control section controls the sequence in which the instructions stored in program memory are executed. The 16-bit program counter (PC) holds the address of the next instruction to be executed. The conditional branch logic enables internal and external events to the processor to cause a change in the program execution sequence.

Additionally to the CPU functionality of the 8051 standard microcontroller, the C868 contains 8 datapointers. For complex applications with peripherals located in the external data memory space or extended data storage capacity, this turned out to be a "bottle neck" for the 8051's communication to the external world. Especially programming in high-level languages (PLM51, C51, PASCAL51) requires extended RAM capacity and at the same time a fast access to this additional RAM because of the reduced code efficiency of these languages.

### Accumulator

ACC is the symbol for the accumulator register. The mnemonics for accumulator-specific instructions, however, refer to the accumulator simply as A.

### Program Status Word

The Program Status Word (PSW) contains several status bits that reflect the current state of the CPU.

**PSW**

**Program Status Word Register**

1	0	Bank 2 selected, data address 10 <sub>H</sub> -17 <sub>H</sub>																
1	1	Bank 3 selected, data address 18 <sub>H</sub> -1F <sub>H</sub>																
<b>F0</b>	5	rw	<b>General Purpose Flag</b>															
<b>AC</b>	6	rwh	<b>Auxiliary Carry Flag</b> Used by instructions which execute BCD operations.															
<b>CY</b>	7	rwh	<b>Carry Flag</b> Used by arithmetic instructions.															

**B Register**

The B register is used during multiply and divide and serves as both source and destination. For other instructions it can be treated as another scratch pad register.

**Stack Pointer**

The stack pointer (SP) register is 8 bits wide. It is incremented before data is stored during PUSH and CALL executions and decremented after data is popped during a POP and RET (RETI) execution, i.e. it always points to the last valid stack byte. While the stack may reside anywhere in the on-chip RAM, the stack pointer is initialized to 07<sub>H</sub> after a reset. This causes the stack to begin a location = 08<sub>H</sub> above register bank zero. The SP can be read or written under software control.

## 2.2 CPU Timing

A machine cycle of the C868 consists of 6 states (12 system clock periods). Each state is divided into a phase 1 half and a phase 2 half. Thus, a machine cycle consists of 12 internal clock periods, numbered S1P1 (state 1, phase 1) through S6P2 (state 6, phase 2). Each state lasts two internal clock periods. Typically, arithmetic and logic operations take place during phase 1 and internal register-to-register transfers take place during phase 2.

The diagrams in **Figure 2-2** show the fetch/execute timing related to the internal states and phases. Since these internal clock signals are not user-accessible, the ALE (address latch enable) signal are shown for external reference. ALE is normally activated twice during each machine cycle: once during S1P2 and S2P1, and again during S4P2 and S5P1.

Execution of a one-cycle instruction begins at S1P2, when the op-code is latched into the instruction register. If it is a two-byte instruction, the second reading takes place during S4 of the same machine cycle. If it is a one-byte instruction, there is still a fetch at S4, but the byte read (which would be the next op-code) is ignored (discarded fetch), and the program counter is not incremented. In any case, execution is completed at the end of S6P2.

**Figure 2-2 (a)** and **(b)** show the timing of a 1-byte, 1-cycle instruction and for a 2-byte, 1-cycle instruction.

Most C868 instructions are executed in one cycle. MUL (multiply) and DIV (divide) are the only instructions that take more than two cycles to complete; they take four cycles. Normally two code bytes are fetched from the program memory during every machine cycle. The only exception to this is when a MOVX instruction is executed. MOVX is a one-byte, 2-cycle instruction that accesses external data memory. During a MOVX, the two fetches in the second cycle are skipped while the external data memory is being addressed and strobed. **Figure 2-2 (c)** and **(d)** show the timing for a normal 1-byte, 2-cycle instruction and for a MOVX instruction.

Figure 2-2 Fetch Execute Sequence

### 3 Memory Organization

The C868 CPU manipulates operands in the following five address spaces:

- up to 8 Kbyte of RAM internal program memory : 8K ROM for C868-1R  
: 8K RAM for C868-1S
- 4 Kbyte of internal Self test and Boot ROM
- 256 bytes of internal data memory
- 256 bytes of internal XRAM data memory
- 128 byte special function register area

Figure 3-1 illustrates the memory address spaces of the C868.

Figure 3-1 C868 Memory Map

The internal Self Test and Boot ROM overlaps the internal program memory in the address range from 0000<sub>H</sub> to 0FFF<sub>H</sub>. Depending on the selected operating mode (chipmode), either internal program memory or the internal Self Test and Boot ROM is accessed in this address range.

### 3.1 Program Memory, “Code Space”

The C868-1S has 8 Kbytes of random access program memory (RAM) and 4 Kbytes of Boot and Self Test ROM. In the normal mode the C868-1S executes program code out of the internal RAM.

The Boot ROM includes a bootstrap loader program for the bootstrap loader of the C868-1S. The software routines of the bootstrap loader program allow the easy and quick programming or loading of the internal program RAM via the serial interface while the MCU is in-circuit.

The C868-1R has 8Kbytes of ROM and 4 Kbytes of Self Test ROM.

The Self Test ROM has a self test program for the self test mode of the C868.

### 3.2 Data Memory, “Data Space”

The data memory address space consists of an internal and an external(XRAM) memory space. The internal data memory is divided into three physically separate and distinct blocks: the lower 128 bytes of RAM, the upper 128 bytes of RAM, and the 128 byte special function register (SFR) area.

While the upper 128 bytes of data memory and the SFR area share the same address locations, they are accessed through different addressing modes. The lower 128 bytes of data memory can be accessed through direct or register indirect addressing; the upper 128 bytes of RAM can be accessed through register indirect addressing only; the special function registers are accessible through direct addressing. Four 8-register banks, each bank consisting of eight 8-bit multi-purpose registers, occupy locations 00<sub>H</sub> through 1F<sub>H</sub> in the lower RAM area. The next 16 bytes, locations 20<sub>H</sub> through 2F<sub>H</sub>, contain 128 directly addressable bit locations. The stack can be located anywhere in the internal data memory address space, and the stack depth can be expanded up to 256 bytes.

The internal XRAM is located in the in the external data memory area and must be accessed by external data memory instructions (MOVX).

#### 3.2.1 General Purpose Registers

The lower 32 locations of the internal RAM are assigned to four banks with eight general purpose registers (GPRs) each. Only one of these banks may be enabled at a time. Two bits in the program status word, RS0 and RS1, select the active register bank. This allows fast context switching, which is useful when entering subroutines or interrupt service routines.

The 8 general purpose registers of the selected register bank may be accessed by register addressing. With register addressing the instruction opcode indicates which register is to be used. For indirect addressing R0 and R1 are used as pointer or index register to address internal or external memory (e.g. MOV @R0).

## Memory Organization

Reset initializes the stack pointer to location 07<sub>H</sub> and increments it once to start from location 08<sub>H</sub> which is also the first register (R0) of register bank 1. Thus, if one is going to use more than one register bank, the SP should be initialized to a different location of the RAM which is not used for data storage.

### 3.3 Program and Data Memory Organisation

The C868 can operate in four different operating modes (chipmodes) with different program and data memory organisations:

- Normal Mode
- Normal XRAM Mode
- Bootstrap Mode
- Bootstrap XRAM Mode

#### 3.3.1 Special function register SYSCON1

There are four control bits located in SFR SYSCON1 which control the code and data memory organisation of the C868. Two of these bits (BSLEN and SWAP) cannot be programmed as normal bits but with a special software unlock sequence. The special software unlock sequence was implemented to prevent unintentional changing of these bits and consists of consecutive followed instructions which have to set set two dedicated enable bits.

#### SYSCON1

##### System Control Register 1

[Reset value: 00XXX0X0<sub>B</sub>]

7	6	5	4	3	2	1	0
<b>ESWC</b>	<b>SWC</b>	-	-	-	<b>BSLEN</b>	-	<b>SWAP</b>
w	w	r	r	r	rw	r	rw

Field	Bits	Typ	Description
<b>SWAP</b>	0	rw	<p><b>SWAP Code and Data Memory</b></p> <p>SWAP = 0 : Code and data memory are in their standard locations (default)</p> <p>SWAP = 1 : Code and data memory are swapped</p> <p>The modification of this bit is by software only and must be completed by the special software unlock sequence in order to effect the mode change. Otherwise, this bit automatically reverts to its previous value with the third EOI (end of instruction) after this bit is modified. This is to prevent any incorrect status read.</p>

Memory Organization

Field	Bits	Typ	Description
<b>BSLEN</b>	2	rw	<p><b>Bootstrap Mode Enable</b>            BSLEN = 1 : Bootstrap mode            BSLEN = 0 : Normal mode (default)</p> <p>This bit is initialised to the reverse of the value at external pin ALE/BSL latched at the rising edge of RESET. This bit can be set/cleared by software to change between the modes. The modification of this bit by software must be completed by the special software unlock sequence in order to effect the mode change. Otherwise, this bit automatically reverts to its previous value with the third EOI (end of instruction) after this bit is modified. This is to prevent any incorrect status read.</p>
<b>SWC</b>	6	w	<p><b>Switch Mode</b></p> <p>The SWC bit must be set as the second instruction in a special software unlock sequence directly after having set bit ESWC. The new chipmode becomes active after the second EOI (end of instruction) after this event and the SWC bit is also cleared simultaneously.</p> <p>SWC is a write only bit. Reading SWC returns a '0'.</p>
<b>ESWC</b>	7	w	<p><b>Enable Switch Mode</b></p> <p>The ESWC bit must be set during the first instruction in the special software unlock sequence. The bit ESWC will be cleared by hardware with the third EOI (end of instruction) after this event.</p> <p>ESWC is a write only bit. Reading ESWC returns a '0'.</p>
-	[7:2]	r	<p><b>reserved;</b>            returns '0' if read; should be written with '0';</p>

### 3.3.2 Chip Modes

The various chip modes supported are shown in [Figure 3-2](#).

**Figure 3-2 Entry and exit of Chip Modes**

A valid hardware reset would, of course, override any of the above entry or exit procedures.

**Table 3-1 Hardware and Software Selection of Chipmodes**

Operating Mode (Chipmode)	Hardware Selection	Software Selection
Normal Mode	ALE/BSL pin = high RESET rising edge	ALE/BSL = don't care; setting bits BSLEN, SWAP = 0,0; execute unlocking sequence
Normal XRAM Mode	Not possible	setting bits BSLEN, SWAP = 0,1; execute unlocking sequence
Bootstrap XRAM Mode	Not possible	setting bits BSLEN, SWAP = 1,1; execute unlocking sequence
Bootstrap Mode	ALE/BSL pin = low RESET rising edge	ALE/BSL = don't care; setting bits BSLEN, SWAP = 1,0; execute unlocking sequence

### 3.3.2.1 Normal Mode

The normal mode is the standard 8051 compatible operating mode of the C800.

**Table 3-2 Normal Memory Configuration for C868**

Memory Space	Memory Boundary
Code Space	RAM/ROM: 0000 <sub>H</sub> to 1FFF <sub>H</sub>
Internal Data Space	XRAM: FF00 <sub>H</sub> to FFFF <sub>H</sub>

### 3.3.2.2 Bootstrap Mode

In the bootstrap mode, code is fetched from the boot-ROM when PC is less than 1000<sub>H</sub>. A dedicated 4 Kbyte boot-ROM is implemented to support this function. The actual code inside the boot-ROM could be made up of various components such as programming code for RAM module, download code, initialization routines or diagnostic software.

The bootstrap mode can be entered via one of the possible ways:

- hardware start-up sequence, or
- software entry using special unlock sequence

The exit from the bootstrap mode is possible via one of the possible ways:

- hardware reset, or
- software using special unlock sequence

The memory mapping for this mode is shown in the [Table 3-3](#)

**Table 3-3 Bootstrap Memory Configuration for C868-1R**

Memory Space	Memory Boundary
Code Space	Boot ROM: 0000 <sub>H</sub> to 0FFF <sub>H</sub>
Internal Data Space	XRAM: FF00 <sub>H</sub> to FFFF <sub>H</sub> , ROM/RAM: 0000 <sub>H</sub> to 1FFF <sub>H</sub>

Once in the bootstrap mode, the on-chip XRAM is always enabled irrespective of the XMAP0 bit in SFR SYSCON0. Exiting the bootstrap mode via software, the on-chip XRAM access returns to the state prior to entering this mode, depending on XMAP0.

### 3.3.2.3 XRAM Modes

In the XRAM modes, code and data memory are swapped and in this case the code can be fetched from the data space. This is useful for running diagnostic software.

The entry and exit into this mode is always through the special software unlock sequence. The XRAM mode could be entered from either the normal mode or the

**Memory Organization**

bootstrap mode. **Table 3-4** and **Table 3-5** show the various memory configurations respectively in an example.

**Table 3-4 Normal XRAM Mode**

Memory Space	Memory Boundary
Code Space	XRAM: FF00 <sub>H</sub> to FFFF <sub>H</sub>
Data Space	ROM/RAM: 0000 <sub>H</sub> to 1FFF <sub>H</sub>

**Table 3-5 Bootstrap XRAM Mode**

Memory Space	Memory Boundary
Code Space	Boot ROM: 0000 <sub>H</sub> to 0FFF <sub>H</sub> XRAM: FF00 <sub>H</sub> to FFFF <sub>H</sub>
Data Space	RAM/ROM: 0000 <sub>H</sub> to 1FFF <sub>H</sub>

The on-chip XRAM, which is in the upper part of the 64 KB data space, is always enabled in this mode for code access irrespective of the XMAP0 bit. The external data space also becomes code space.

The actual physical sizes of the various memory types as mentioned above are product specific. In the C868, the external accesses are prohibited. For code spaces, appropriate branch instructions must therefore be inserted.

The on-chip data space is accessible, as usual, via MOVX instructions. The on-chip data memory accesses to RAM/ROM are restricted by the physical memory available in the respective product. For the C868-1R, the option to disable the access to the ROM is selectable upon request. This option is reflected in SFR Version bit 7(1 for access disabled).

An exit from the XRAM mode is possible by software only. In this mode the on-chip XRAM is disabled as data space irrespective of XMAP0 bit in SFR SYSCON0. It will remain disabled after exit from XRAM mode unless the XMAP0 had been cleared prior to entering this mode.

### 3.3.2.4 Software Unlock Sequence

A special software unlock sequence is required to enter or exit the various chip modes supported.

The bits ESWC and SWC in SFR SYSCON1 are implemented in a way to prevent unintentional changing of the bits SWAP and BSLEN. Any change of the bits SWAP or BSLEN not accompanied by the software unlock sequence will have no effect and the above bits will revert back to their previous values two instructions after being changed.

The following programming steps must be executed at the ESWC/SWC unlock sequence:

#### i) First Instruction:

This instruction should set the ESWC bit and modify of SWAP and/or BSLEN, as necessary.

```
MOV SYSCON1,#10000X0YB ;X is BSLEN, Y is SWAP
```

#### ii) Second Instruction :

The second instruction must set the SWC bit. If this instruction sequence is followed, then only the mode change in the previous instructions will come into effect. Otherwise the previous mode will be retained and both bits ESWC and SWC are cleared.

The new chip mode becomes effective after the end of the second instruction after the writing of the bit SWC.

```
MOV SYSCON1,#11000X0YB ;X is BSLEN, Y is SWAP
```

#### iii) Third Instruction:

The instruction following this sequence should be used for initialization of the program counter to the 16 bit start-address of the new code memory resource, e.g. with :

```
LJMP 0XXXXH ;XXXX is the 16-bit hexadecimal address in new code memory
```

If both SWAP and BSLEN bits are set in the first instruction, both modes will still be entered. It is, in any case, the responsibility of the user to provide the appropriate relocation address depending on the mode prior to the execution of this sequence. The special software unlock instruction sequence cannot be interrupted by an interrupt request. Any read or write operation to SFR SYSCON1 will block the interrupt generation for the first cycle of the directly following instruction. Therefore, the response time of an interrupt request may be additionally delayed.

### 3.4 Special Function Registers

All registers, except the program counter and the four general purpose register banks, reside in the special function register area. The special function register area consists of two portions: the standard special function register area and the mapped special function register area. For accessing the mapped special function area, bit RMAP in special function register SYSCON0 must be set. All other special function registers are located in the standard special function register area which is accessed when RMAP is cleared ("0").

#### SYSCON0

#### System Control Register 0

[Reset value: XX10XXX1<sub>B</sub>]

7	6	5	4	3	2	1	0
-	-	<b>EALE</b>	<b>RMAP</b>	-	-	-	<b>XMAP0</b>
r	r	rw	rw	r	r	r	rw

The functions of the shaded bits are not described here

Field	Bits	Typ	Description
<b>RMAP</b>	4	rw	<b>Special Function Register Map Control</b> RMAP = 0 : The access to the non-mapped (standard) special function register area is enabled. RMAP = 1 : The access to the mapped special function register area is enabled.
-	[7:2]	r	<b>reserved;</b> returns '0' if read; should be written with '0';

As long as bit RMAP is set, the mapped special function register area can be accessed. This bit is not cleared automatically by hardware. Thus, when non-mapped/mapped registers are to be accessed, the bit RMAP must be cleared/set respectively by software.

The 109 special function registers (SFR) include pointers and registers that provide an interface between the CPU and the other on-chip peripherals. All available SFRs whose address bits 0-2 are 0 (e.g. 80<sub>H</sub>, 88<sub>H</sub>, 90<sub>H</sub>, ..., F0<sub>H</sub>, F8<sub>H</sub>) are bit-addressable. Totally there are 128 directly addressable bits within the SFR area.

All SFRs are listed in [Table 3-6](#) and [Table 3-7](#).

In [Table 3-6](#) they are organized in groups which refer to the functional blocks of the C868-1R, C868-1S. [Table 3-7](#) illustrates the contents (bits) of the SFRs

## 4 On-Chip Peripheral Components

This chapter gives detailed information about all on-chip peripherals of the C868 except for the integrated interrupt controller, which is described separately in chapter 7.

### 4.1 Ports

The C868 has two kinds of ports. The first kind is push-pull ports instead of the traditional quasi-bidirectional ports. The ports belonging to this kind is port 1 which is a 5-bit I/O port and port 3 which is an eight-bit I/O port. When configured as inputs, these ports will be high impedance with Schmitt trigger feature. Port 3 is alternate for capture/compare functions whereas, port 1 has alternate functions for some of the pins.

The second kind is dedicated ports which are shared by the interrupts, timer 2 inputs, capture/compare hall inputs and analog inputs.

### 4.2 I/O Ports

Port 1 and 3 are push-pull ports. Port 1 and port 3 can function as normal I/O ports which have associated SFRs at address 90<sub>H</sub> and B0<sub>H</sub> respectively. These ports also have alternate functions as listed in [Table 4-2](#).

There are three SFRs dedicated for each of these ports. The first one is the port latch (P1/P3) and second one is direction control register (P1DIR/P3DIR) which is used to set the direction for each pin. In P1DIR/P3DIR, if the bit is set to 0 the respective port pin is an output, and 1 means an input. After reset, by default all the Port 1 and 3 pins are input. The third one is the alternate function register (P1ALT/P3ALT) which is used to set the function of each pin. When used as alternate function, the direction of the pins has to be set accordingly.

When the bit is set an input, any read operation will return the value at the port. When the bit is set as an output, a read operation will return the latched value if it is part of a read-modify-write operation, otherwise a read operation will return the value at the port.

*Note: While in the idle mode or the power down mode the I/O ports hold the last values.*

### 4.2.1 Register Overview

The following table lists the port SFR registers. They contain the value in the port latches.

**Table 4-1 Memory Organization Register Overview**

Register	Description	Address
P1	Port 1 SFR	90 <sub>H</sub>
P1DIR	Port 1 Direction	90 <sub>H</sub>
P3	Port 3 SFR	B0 <sub>H</sub>
P3DIR	Port 3 Direction	B0 <sub>H</sub>
P3ALT	Port 3 Alternate Function	B1 <sub>H</sub>
P1ALT	Port 1 Alternate Function	B4 <sub>H</sub>

P1 and P1DIR is mapped on the same address and depend on the RMAP (SYSCON0.4) bit to select between the two registers. By default (bit = 0), P1 occupies the address. If the bit is set to 1 then P1DIR occupy the address.

P3 and P3DIR is mapped on the same address and depend on the RMAP (SYSCON0.4) bit to select between the two registers. By default (bit = 0), P3 occupies the address. If the bit is set to 1 then P3DIR occupy the address.

Ports 1 and 3 also serves alternate functions as listed in the [Table 4-2](#). To select between the alternate function and normal I/O, registers P1ALT and P3ALT are used. Each can be set to '1' for alternate functions, or reset to '0' for normal I/O.

**Table 4-2 Ports 1 and 3 Alternate Functions**

Port	Pin	Alt-Function	Description
1	P1.0	TxD	Transmit data of serial interface
1	P1.1	EXF2	Timer 2 overflow flag
1	P1.3	INT3	Interrupt 3
1	P1.4	RxD	Receive data of serial interface
3	P3.0	COUT63	16 bit compare channel output
3	P3.1	CTRAP	CCU trap input
3	P3.2	COUT62	Output of CCU6 channel 2
3	P3.3	CC62	Input/output of CCU6 channel 2
3	P3.4	COUT61	Output of CCU6 channel 1
3	P3.5	CC61	Input/output of CCU6 channel 1
3	P3.6	COUT60	Output of CCU6 channel 0
3	P3.7	CC60	Input/output of CCU6 channel 0

**P1**

**Port 1 Register**

[Reset value: XXX11111<sub>B</sub>]

**Port 3 Direction Register**

[Reset value: FF<sub>H</sub>]

Field	Bits	Typ	Description
P3DIR	[7:0]	rw	<b>Port 3 Direction Register.</b> This SFR appears at address B0 <sub>H</sub> , only if bit RMAP (SYSCON0.4) is '1' 0: The associated pin is an output. 1: The associated pin is an input (default).

On-Chip Peripheral Components

**P1ALT**

**Port 1 Alternate Function Register**

[Reset value: XXX00X00<sub>B</sub>]

Field	Bits	Typ	Description
<b>P1ALT.1-0</b> <b>P1ALT.4-3</b>	[1:0] [4:3]	rw	<b>Port 1 Alternate Function Switch</b> 0: The associated pin is a normal I/O. (default) 1: The associated pin is an alternate function. Please see <a href="#">Table 4-2</a> . All the other bits in this register are reserved for the future use.
-	[7:5],2	r	<b>reserved;</b> returns '0' if read; should be written with '0';

**P3ALT**

**Port 3 Alternate Function Register**

[Reset value: 00<sub>H</sub>]

Field	Bits	Typ	Description
<b>P3ALT</b>	[7:0]	rw	<b>Port 3 Alternate Function Switch</b> 0: The associated pin is a normal I/O. (default) 1: The associated pin is an alternate function. Please see <a href="#">Table 4-2</a> .

### **4.3 Dedicated Ports**

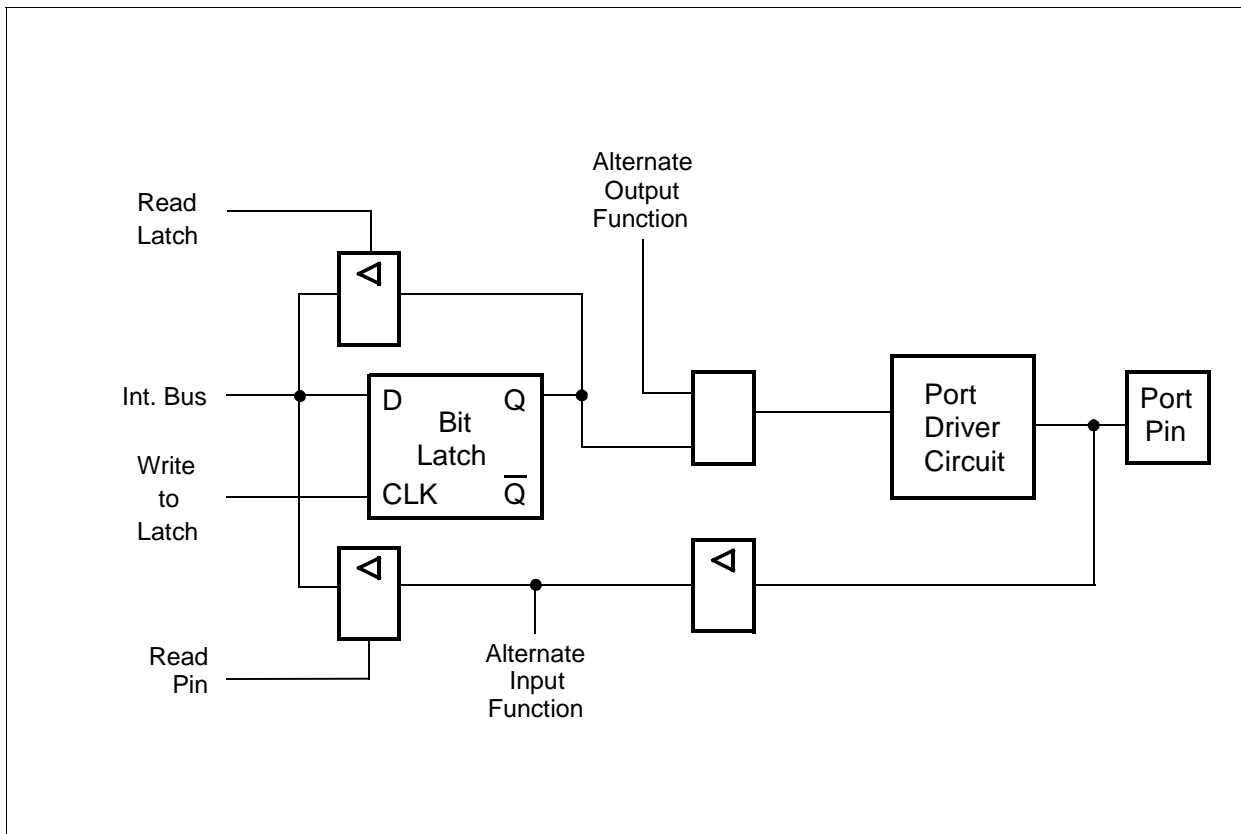

Beside I/O Port, the rest of the ports are dedicated ports. These dedicated ports do not require bit latches as it uses the 'alternate access'.

ANALOG[4:0]: These are pure analog inputs to the ADC module. The signals from the pin should be rightaway directed to the ADC module. These pins are used as digital input for the interrupts, hall inputs to the CCU6 module and inputs to the timer 2 module.

### 4.4 Port 1, Port 3 Circuitry

The pins of ports 1 and 3 are multifunctional. They are port pins and also serve to implement special features as listed in [Table 4-2](#). [Figure 4-1](#) shows a functional diagram of a typical bit latch and I/O buffer, which is the core of the I/O-ports. The bit latch (one bit in the port's SFR) is represented as a type-D flip-flop, which will clock in a value from the internal bus in response to a "write-to-latch" signal from the CPU. The Q output of the flip-flop is placed on the internal bus in response to a "read-latch" signal from the CPU. The level of the port pin itself is placed on the internal bus in response to a "read-pin" signal from the CPU. Some instructions that read from a port (i.e. from the corresponding port SFR P1 and P3) activate the "read-latch" signal, while others activate the "read-pin" signal.

[Figure 4-1](#) shows a functional diagram of a port latch with alternate function.

**Figure 4-1** Ports 1 and 3

### 4.4.1 Read-Modify-Write Feature of Ports

Some port-reading instructions read the latch and others read the pin. The instructions reading the latch rather than the pin read a value, possibly change it, and then rewrite it to the latch. These are called "read-modify-write"- instructions, which are listed in 4-3. If the destination is a port or a port pin, these instructions read the latch rather than the pin. Note that all other instructions which can be used to read a port, exclusively read the port pin. In any case, reading from latch or pin, resp., is performed by reading the SFR P3; for example, "MOV A, P3" reads the value from port 3 pins, while "ANL P3, #0AAH" reads from the latch, modifies the value and writes it back to the latch.

It is not obvious that the last three instructions in [Figure 4-3](#) are read-modify-write instructions, but they are. The reason is that they read the port byte, all 8 bits, modify the addressed bit, then write the complete byte back to the latch.

**Table 4-3 "Read-Modify-Write"-Instructions**

Instruction	Function
ANL	Logic AND; e.g. ANL P1, A
ORL	Logic OR; e.g. ORL P2, A
XRL	Logic exclusive OR; e.g. XRL P3, A
JBC	Jump if bit is set and clear bit; e.g. JBC P1.1, LABEL
CPL	Complement bit; e.g. CPL P3.0
INC	Increment byte; e.g. INC P4
DEC	Decrement byte; e.g. DEC P5
DJNZ	Decrement and jump if not zero; e.g. DJNZ P3, LABEL
MOV Px.y,C	Move carry bit to bit y of port x
CLR Px.y	Clear bit y of port x
SETB Px.y	Set bit y of port x

The reason why read-modify-write instructions are directed to the latch rather than the pin is to avoid a possible misinterpretation of the voltage level at the pin. For example, a port bit might be used to drive the base of a transistor. When a "1" is written to the bit, the transistor is turned on. If the CPU then reads the same port bit at the pin rather than the latch, it will read the base voltage of the transistor (approx. 0.7 V, i.e. a logic low level!) and interpret it as "0". For example, when modifying a port bit by a SETB or CLR instruction, another bit in this port with the above mentioned configuration might be changed if the value read from the pin were written back to the latch. However, reading the latch rather than the pin will return the correct value of "1".

## 4.5 Timers/Counters

The C868 contains three 16-bit timers/counters, timer 0, timer 1 and timer/counter 2, which are useful in many applications for timing and counting.

The timer register is incremented every machine cycle. Thus one can think of it as counting machine cycles. Since a machine cycle consists of 12 periods, the counter rate is 1/12 of the system frequency.

### 4.5.1 Timer 0 and 1

Timer 0 and 1 of the C868 are fully compatible with timer 0 and 1 can be used in the same four operating modes:

Mode 0:8-bit timer with a divide-by-32 prescaler

Mode 1:16-bit timer

Mode 2:8-bit timer with 8-bit auto-reload

Mode 3:Timer 0 is configured as two 8-bit timers. Timer 1 in this mode holds its count. The effect is the same as setting  $TR1 = 0$ .

External inputs  $\overline{INT0}$  and  $\overline{INT1}$  can be programmed to function as a gate for timer 0 and 1 to facilitate pulse width measurements.

Each timer consists of two 8-bit registers (TH0 and TL0 for timer 0, TH1 and TL1 for timer 1) which may be combined to one timer configuration depending on the mode that is established. The functions of the timers are controlled by two special function registers TCON and TMOD.

In the following descriptions the symbols TH0 and TL0 are used to specify the high-byte and the low-byte of timer 0 (TH1 and TL1 for timer 1, respectively). The operating modes are described and shown for timer 0. If not explicitly noted, this applies also to timer 1.

### 4.5.1.1 Timer 0 and 1 Registers

Totally seven special function registers control the timer 0 and 1 operation :

- TL0/TH0 and TL1/TH1 - timer registers, low and high part
- TCON and IEN0 - control and interrupt enable
- TMOD - mode select

### 4.5.1.2 Mode 0

Putting either timer 0, 1 into mode 0 configures it as an 8-bit timer with a divide-by-32 prescaler. **Figure 4-2** shows the mode 0 operation.

In this mode, the timer register is configured as a 13-bit register. As the count rolls over from all 1's to all 0's, it sets the timer overflow flag TF0. The overflow flag TF0 then can be used to request an interrupt. The counted input is enabled to the timer when TR0 = 1 and either Gate = 0 or INT0 = 1 (setting Gate = 1 allows the timer to be controlled by external input INT0, to facilitate pulse width measurements). TR0 is a control bit in the special function register TCON; Gate is in TMOD.

The 13-bit register consists of all 8 bits of TH0 and the lower 5 bits of TL0. The upper 3 bits of TL0 are indeterminate and should be ignored. Setting the run flag (TR0) does not clear the registers.

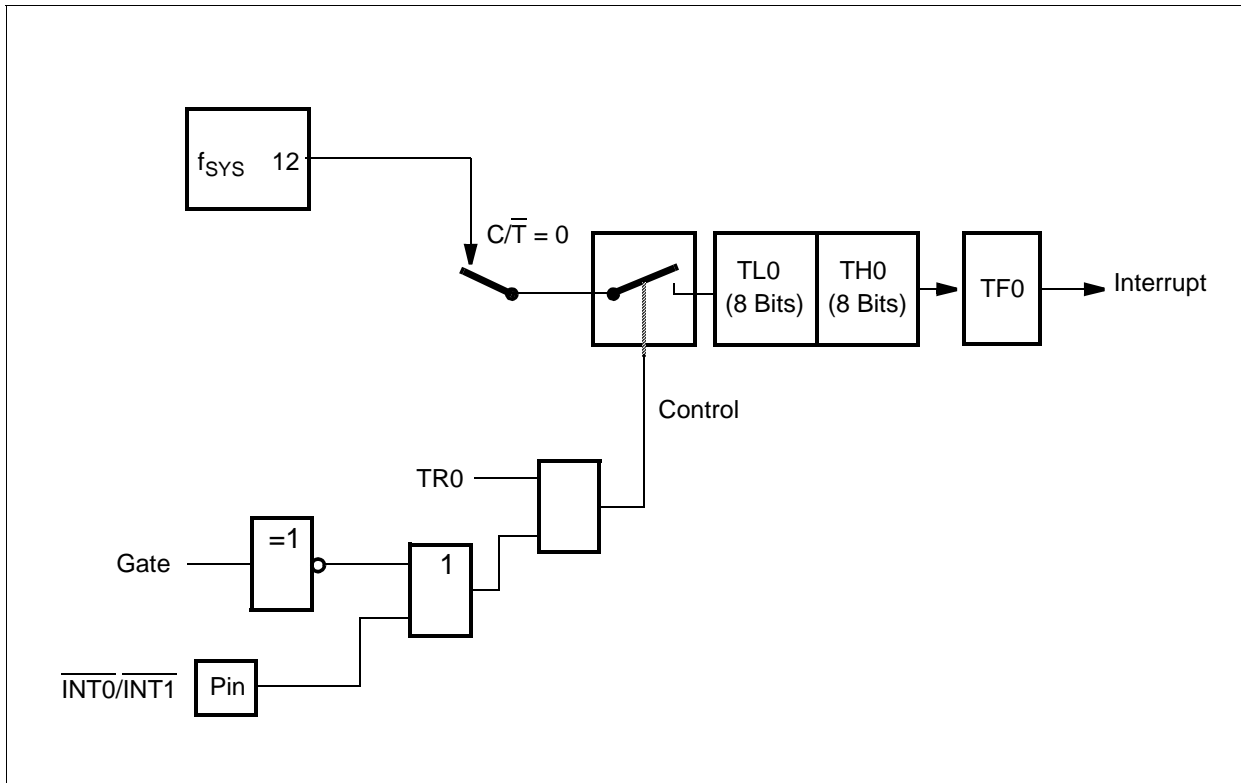

Mode 0 operation is the same for timer 0 as for timer 1. Substitute TR0, TF0, TH0, TL0 and INT0 for the corresponding timer 1 signals in **Figure 4-2**. There are two different gate bits, one for timer 1 (TMOD.7) and one for timer 0 (TMOD.3).

**Figure 4-2** Timer 0, Mode 0: 13-Bit Timer

### 4.5.1.3 Mode 1

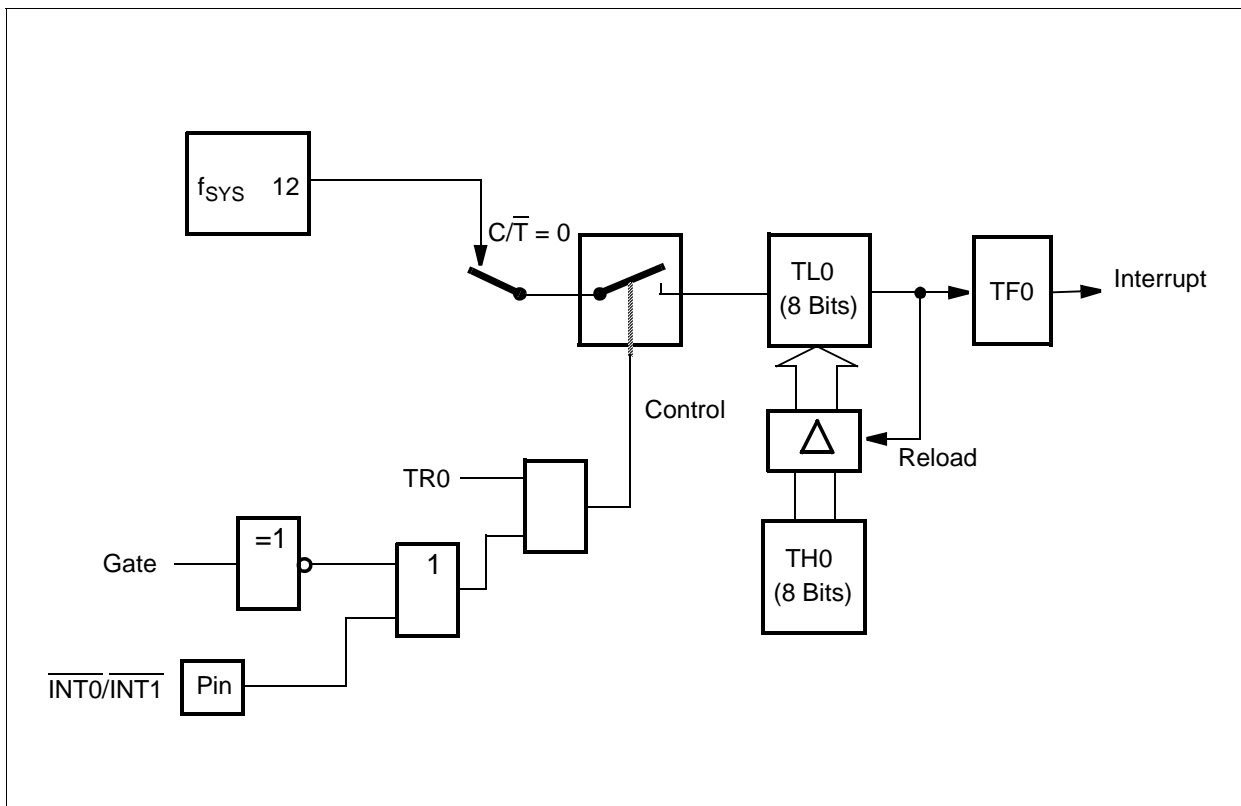

Mode 1 is the same as mode 0, except that the timer register is running with all 16 bits. Mode 1 is shown in [Figure 4-3](#).

**Figure 4-3** Timer 0, Mode 1: 16-Bit Timer/Counter

### 4.5.1.4 Mode 2

Mode 2 configures the timer register as an 8-bit counter (TL0) with automatic reload, as shown in **Figure 4-4**. Overflow from TL0 not only sets TF0, but also reloads TL0 with the contents of TH0, which is preset by software. The reload leaves TH0 unchanged.

**Figure 4-4** Timer 0,1, Mode 2: 8-Bit Timer/Counter with Auto-Reload

### 4.5.1.5 Mode 3

Mode 3 has different effects on timer 0 and timer 1. Timer 1 in mode 3 simply holds its count. The effect is the same as setting TR1=0. Timer 0 in mode 3 establishes TL0 and TH0 as two separate counters. The logic for mode 3 on timer 0 is shown in [Figure 4-5](#). TL0 uses the timer 0 control bits:  $C/\bar{T}$ , Gate, TR0,  $\overline{INT0}$  and TF0. TH0 is locked into a timer function (counting machine cycles) and takes over the use of TR1 and TF1 from timer 1. Thus, TH0 now controls the "timer 1" interrupt.

Mode 3 is provided for applications requiring an extra 8-bit timer or counter. When timer 0 is in mode 3 and when TR1 is set, timer 1 can be turned on by switching it to any mode other than 3 and off by switching it into its own mode 3, or can still be used by the serial channel as a baud rate generator, or in fact, in any application not requiring an interrupt from timer 1 itself.

**Figure 4-5** Timer 0, Mode 3: Two 8-Bit Timers/Counters

## 4.6 Functional Description of Timer/Counter 2

Timer two serves as a 16-bit timer/counter for which is also capable of being used as a baudrate generator for the UART module.

### 4.6.1 Features

- 16-bit auto-reload mode
  - selectable up or down counting
- one channel 16-bit capture mode
- Baudrate generator for UART
- Timer/counter powerdown in normal, idle and slow-down modes

### 4.6.2 Overview

Timer 2 is a 16-bit general purpose timer/counter which can additionally function as a baudrate generator. This module is functionally compatible to the Timer 2 in the C501 product family.

Timer/counter 2 can function as a timer or counter in each of its modes. As a timer, it counts with an input clock of  $f_{SYS}/12$ . As a counter, it counts 1-to-0 transitions on pin T2. In the counter mode the maximum resolution for the count is  $f_{SYS}/24$ .

### 4.6.3 Register Description

The T2CON register is used for controlling the various modes of timer/counter 2 module. Additionally, this register also indicates the status of the timer/counter 2 functions (flags).

#### 4.6.4 Operating Mode Selection

The operating mode of timer/counter 2 is controlled by register T2CON. This register serves two purposes:

- during initialization it provides access to a set of control bits
- during timer operation it provides access to a set of status flags.

The different modes of operation are:

- Auto-Reload Mode,
- Capture Mode, and
- Baudrate Generator Mode

#### 4.6.5 Auto-Reload Mode

In the auto-reload mode, timer/counter 2 counts to an overflow value and then reloads its registers contents with a 16-bit value start value for a fresh counting sequence. The overflow condition is indicated by setting the bit TF2 in the T2CON register. This will then generate an interrupt request to the core by an active high signal. The overflow flag TF2 must be cleared by software.

The auto-reload mode is further classified into two categories depending upon the DCEN control bit.

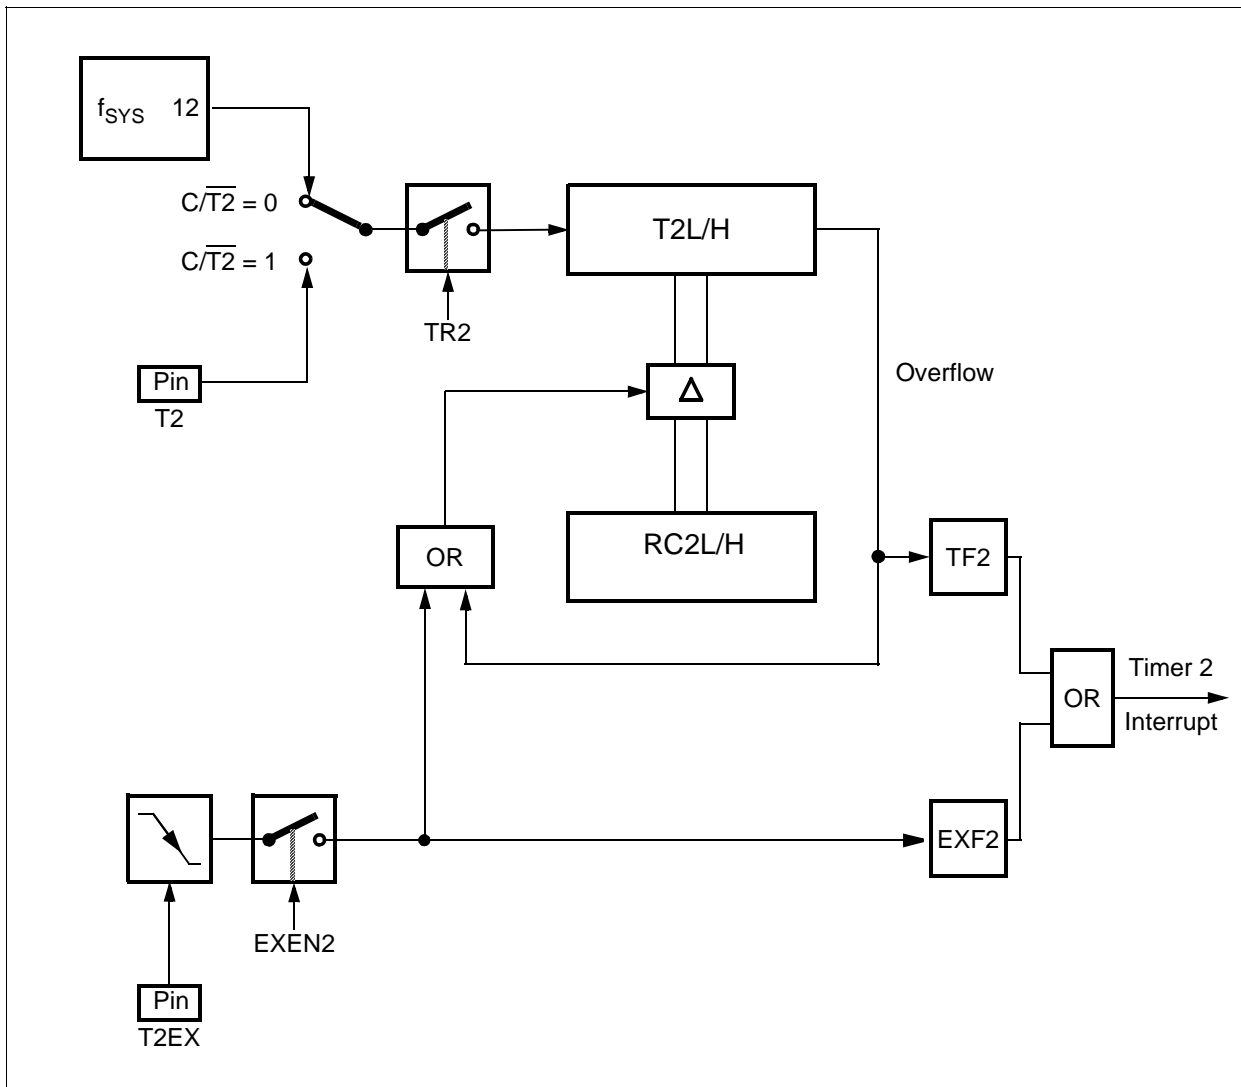

##### 4.6.5.1 Up/Down Count Disabled

If DCEN=0, the up-down count selection is disabled. The timer/counter, therefore, functions as a pure up timer/counter only. The operational block diagram is shown in [Figure 4-6](#).

In this mode if EXEN2=0, the timer/counter starts to count up to a maximum of  $FFFF_H$ , once TR2 is set. Upon overflow, bit TF2 is set and the timer register is reloaded with a 16-bit reload of the RC2L/H registers. A fresh count sequence is started and the timer/counter counts up from this reload value as in the previous count sequence. This reload value is chosen by software, prior to the occurrence of an overflow condition.

If EXEN2=1, the timer/counter counts up to a maximum to  $FFFF_H$ , once TR2 is set. A 16-bit reload of the timer registers from register RC2L/H is triggered either by an overflow condition or by a negative edge at input pin T2EX. If an overflow caused the reload, the overflow flag TF2 is set. If a 1-to-0 transition at pin T2EX caused a reload, bit EXF2 is set. In either case, an interrupt is generated to the core and the timer/counter proceeds to its next count sequence. The EXF2 flag, similar to the TF2, must be cleared by software.

*Note: In counter mode, if the reload via T2EX and the count clock T2 are detected simultaneously the reload takes precedence over the count. The counter increments its value with the following T2 count clock.*

**Figure 4-6 Auto-Reload Mode (DCEN = 0)**

#### 4.6.5.2 Up/Down Count Enabled

If DCEN=1, the up-down count selection is enabled. The direction of count is determined by the level at input pin T2EX. The operational block diagram is shown in [Figure 4-7](#).

A logic 1 at pin T2EX sets the timer/counter 2 to up counting mode. The timer/counter, therefore, counts up to a maximum of  $FFFF_H$ . Upon overflow, bit TF2 is set and the timer/counter registers are reloaded with a 16-bit reload of the RC2L/H registers. A fresh count sequence is started and the timer counts up from this reload value as in the previous count sequence. This reload value is chosen by software, prior to the occurrence of an overflow condition.

A logic 0 at pin T2EX sets the timer/counter 2 to down counting mode. The timer/counter counts down and underflows when the T2L/H value reaches the value stored at registers

### 4.6.6 Capture Mode

In order to enter the 16-bit capture mode, bits  $\overline{CP/RL2}$  and EXEN2 in register T2CON must be set. In this mode, the down count function must remain disabled. The timer/counter functions as a 16-bit timer or counter and always counts up to  $FFFF_H$  and overflows. Upon an overflow condition, bit TF2 is set and the timer/counter reloads its registers with  $0000_H$ . The setting of TF2 generates an interrupt request to the core.

Additionally, with a falling edge on pin T2EX the contents of the timer/counter registers (T2L/H) are captured into the RC2L/H registers. If the capture signal is detected while the counter is being incremented, the counter is first incremented before the capture operation is performed. This ensures that the latest value of the timer/counter registers are always captured.

When the capture operation is completed, bit EXF2 is set and can be used to generate an interrupt request. **Figure 4-8** describes the capture function of timer/counter 2.

**Figure 4-8 Capture Mode**

#### 4.6.7 Baudrate Generator Mode

The baudrate generator mode of timer/counter 2 can be selected by setting the bits TCLK and/or RCLK in register T2CON. So the baudrate for the receive and transmit functions can be individually controlled. The timer/counter itself functions similar to the auto-reload mode with up/down counting is disabled. The timer/counter counts up and overflows but the overflow condition does not set the TF2 flag. An interrupt request to the core is not generated. Upon an overflow condition, the timer/counter registers are reloaded with the RC2L/H registers content and continues counting as before.

The overflow signal is provided as an output of the timer/counter 2 block. This is active for one clock cycle only. Additionally, the status of the TCLK and RCLK bits are also provided as outputs of the timer 2 block. The UART, for e.g., could use these signals to control its baudrates.

The main difference between the auto-reload mode and the baudrate generator mode is that timer 2 as a baudrate generator uses  $f_{SYS}/2$  as the count clock. In the auto-reload mode the timer/counter 2 uses  $f_{SYS}/12$  as the count clock.

If EXEN2=1, in the baudrate generator mode, a falling edge on pin T2EX can be used to generate an interrupt. In this case, flag EXF2 will be set.

*Note: When timer/counter 2 is in the baudrate generator mode, an increment of the timer register happens for every other  $f_{SYS}$ . Therefore, software should not access the T2L/H registers. Software may however, read the RC2L/H registers. Software write into these registers may coincide with a timer update or reload cycle and should therefore be avoided.*

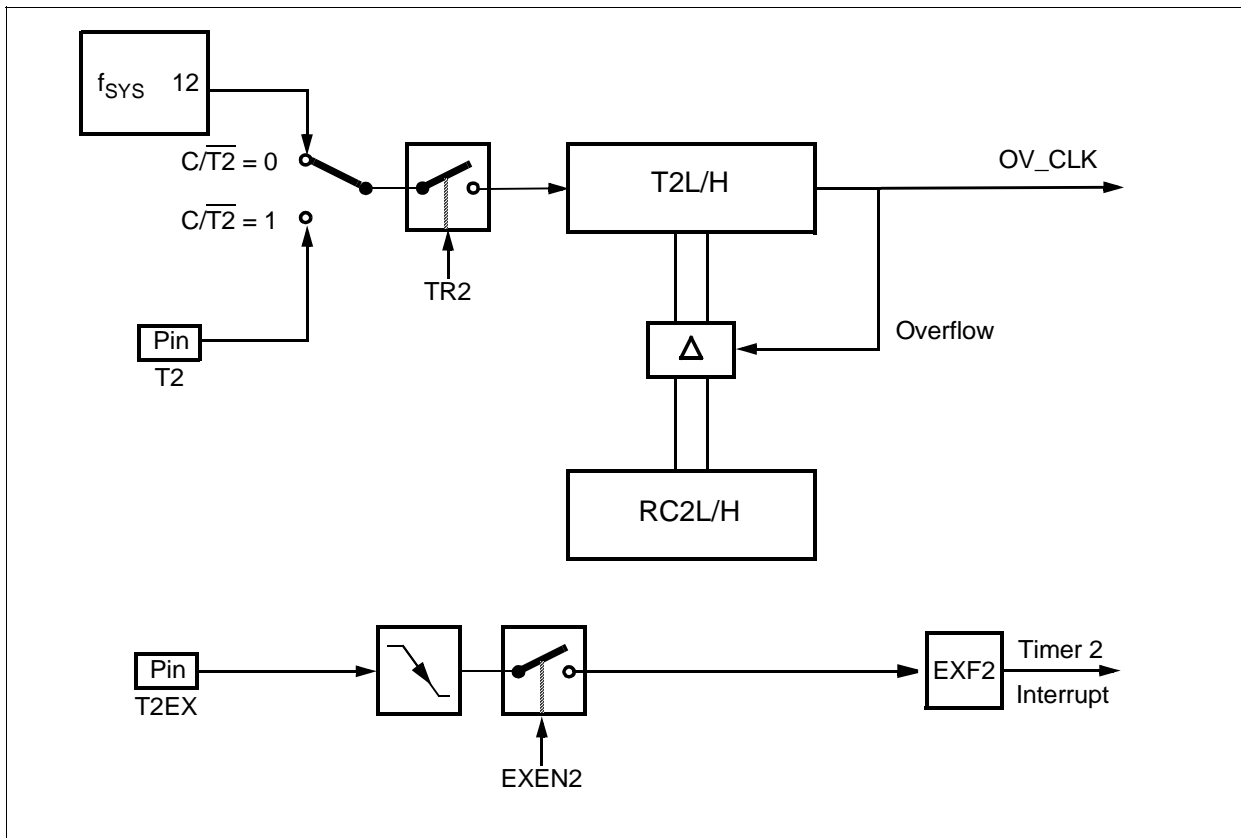

Figure 4-9 Baudrate Generator Mode

### 4.6.8 Count Clock

The count clock for the auto-reload mode is chosen by the bit  $\overline{C/T2}$  in register T2CON. If  $\overline{C/T2} = 0$ , a count clock of  $f_{SYS}/12$  is used for the count operation.

If  $\overline{C/T2} = 1$ , timer 2 behaves as a counter that counts 1-to-0 transitions of input pin T2. The counter samples pin T2 over 2  $f_{SYS}$  cycles. If a 1 was detected during the first clock and a 0 was detected in the following clock, then the counter increments by one. Therefore, the input levels should be stable for at least 1 clocks.

### 4.6.9 Module Powerdown

The timer/counter 2 is disabled when the chip goes into the powerdown mode as describe in . Or it can be individually disabled by setting T2DIS in register PMCON1. This helps to reduce current consumption in the normal, slow down and idle modes of operation if the timer/counter 2 is not utilized. Bit T2ST in register PMCON2 reflects the powerdown status of timer/counter 2.

## 4.7 Capture/Compare Unit (CCU6)

The CCU6 provides two independent timers (T12, T13), which can be used for PWM generation, especially for AC-motor control. Additionally, special control modes for block commutation and multi-phase machines are supported.

### Timer 12 Features

- Three capture/compare channels, each channel can be used either as capture or as compare channel.
- Generation of a three-phase PWM supported (six outputs, individual signals for highside and lowside switches)
- 16 bit resolution, maximum count frequency = system clock
- Dead-time control for each channel to avoid short-circuits in the power stage
- Concurrent update of the required T12/13 registers
- Center-aligned and edge-aligned PWM can be generated
- Single-shot mode supported
- Many interrupt request sources
- Hysteresis-like control mode

### Timer 13 Features

- One independent compare channel with one output
- 16 bit resolution, maximum count frequency = system clock
- Can be synchronized to T12
- Interrupt generation at period-match and compare-match
- Single-shot mode supported

### Additional Features

- Block commutation for Brushless DC-drives implemented
- Position detection via Hall-sensor pattern
- Automatic rotational speed measurement for block commutation
- Integrated error handling
- Fast emergency stop without CPU load via external signal ( $\overline{\text{CTRAP}}$ )
- Control modes for multi-channel AC-drives
- Output levels can be selected and adapted to the power stage
- Capture/compare unit can be powerdown in normal, idle and slow-down modes

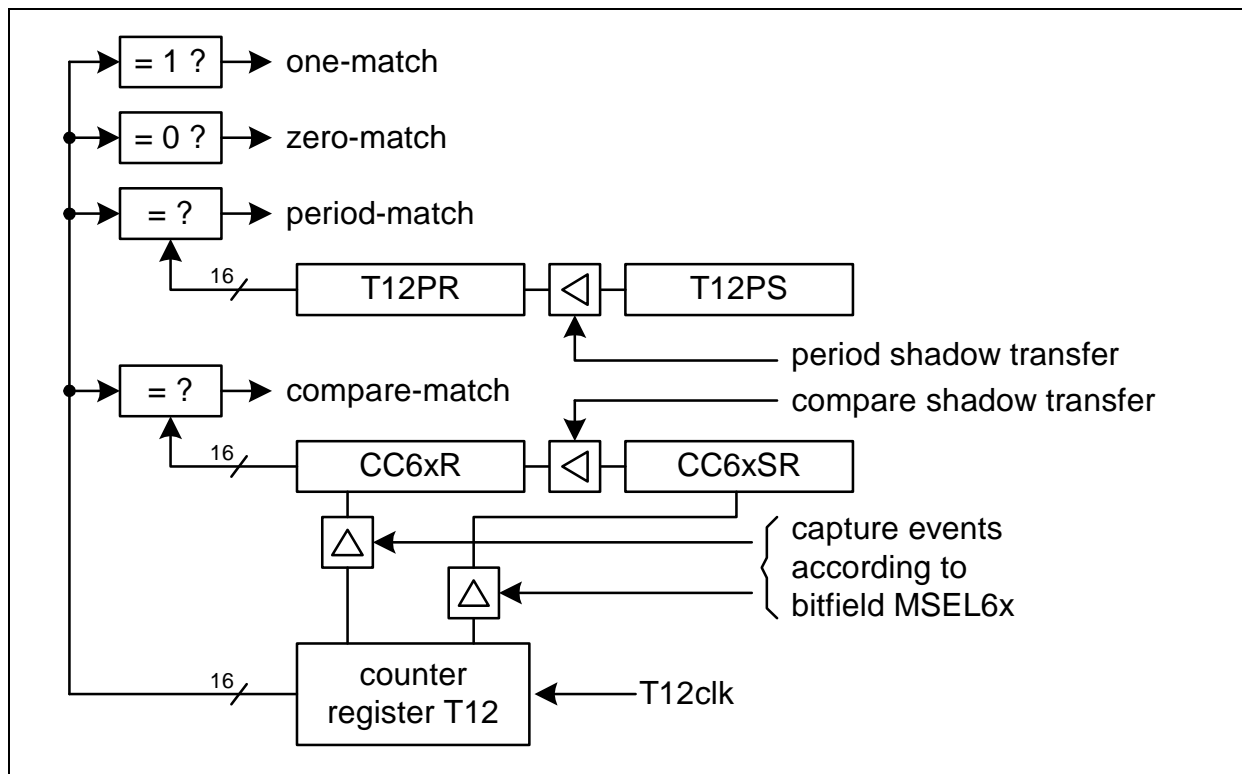

The timer T12 can work in capture and/or compare mode for its three channels. The modes can also be combined. The timer T13 can work in compare mode only. The multi-channel control unit generates output patterns which can be modulated by T12 and/or T13. The modulation sources can be selected and combined (refer to figure 'Modulation Selection, Passive Level and Alternate Output Enable of T12') for the signal modulation.

## 4.7.1 Timer T12

### 4.7.1.1 Overview

The timer T12 is used for capture/compare purposes with three independent channels. The timer T12 is a 16-bit wide counter. Three channel registers (CC60R, CC61R, CC62R), which are built with shadow registers (CC60SR, CC61SR, CC62SR), contain the compare value or the captured timer value. In compare mode, the software writes to the shadow registers and their contents are transferred simultaneously to the actual compare registers during the T12 shadow transfer. In capture mode, the captured value of T12 can be read from the channel registers. The period of the timer T12 is fixed by the period register T12PR, which is also built with a shadow register.

The write access from the CPU targets the corresponding shadow registers, whereas the read access targets the registers actually used (except for the three compare channels, where the actual and the shadow registers can be read).

**Figure 4-10 T12 Overview**

While timer T12 is running, write accesses to register T12 are not taken into account. If the timer T12 is stopped and the dead-time counters are 0, write actions to register T12 are immediately taken into account.

### 4.7.1.2 Counting Rules

Referring to T12 input clock the counting sequence is defined by the following counting rules:

*T12 in edge-aligned mode:*

- The counter is reset to zero and (if desired) the T12 shadow transfer takes place if the period-match is detected. The counting direction is always upwards.

*T12 in center-aligned mode:*

- The count direction is set to counting up (CDIR='0') if the one-match is detected while counting down.
- The count direction is set to counting down (CDIR='1') if the period-match is detected while counting up.
- The counter counts up while CDIR='0' and it counts down while CDIR='1'.
- If enabled the shadow transfer takes place:
  - if the period-match is detected while counting up
  - if the one-match is detected while counting down

The timer T12 prescaler is reset while T12 is not running to ensure reproducible timings and delays.

The counting rules lead to the following sequences:

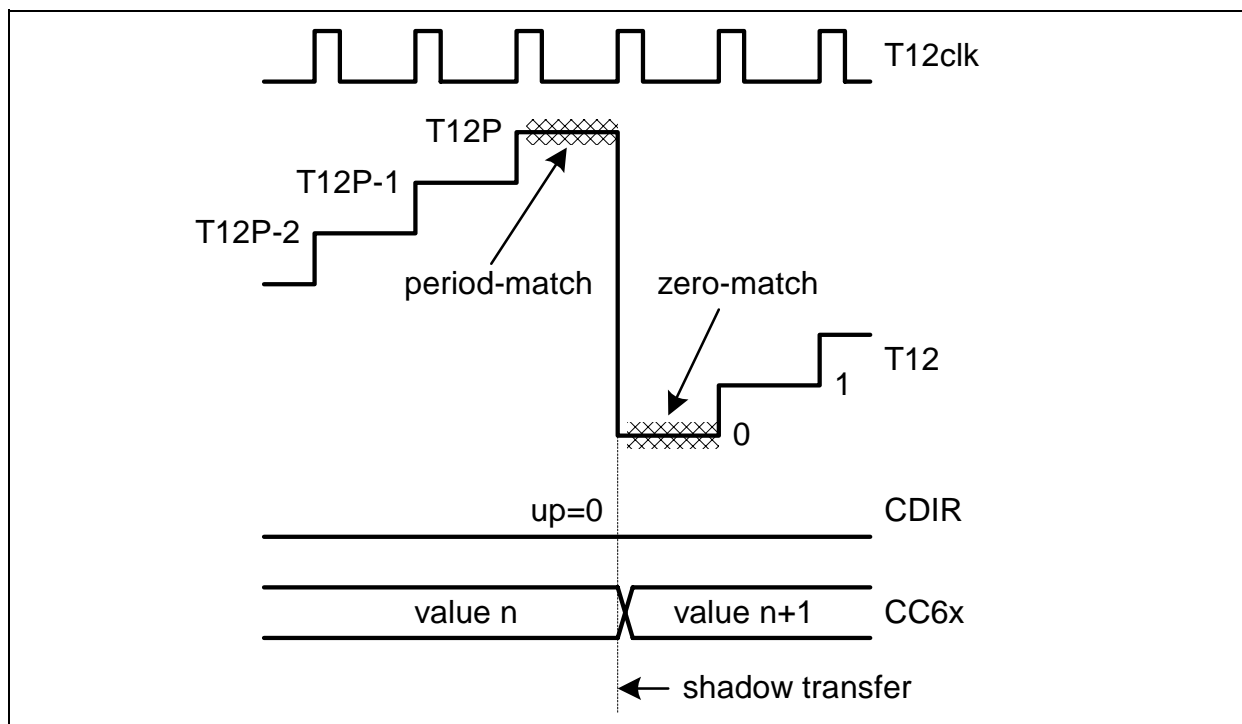

Figure 4-11 T12 in edge-aligned mode

On-Chip Peripheral Components

In the center-aligned mode (T12 counts up and down), the counting rules lead to the following behavior:

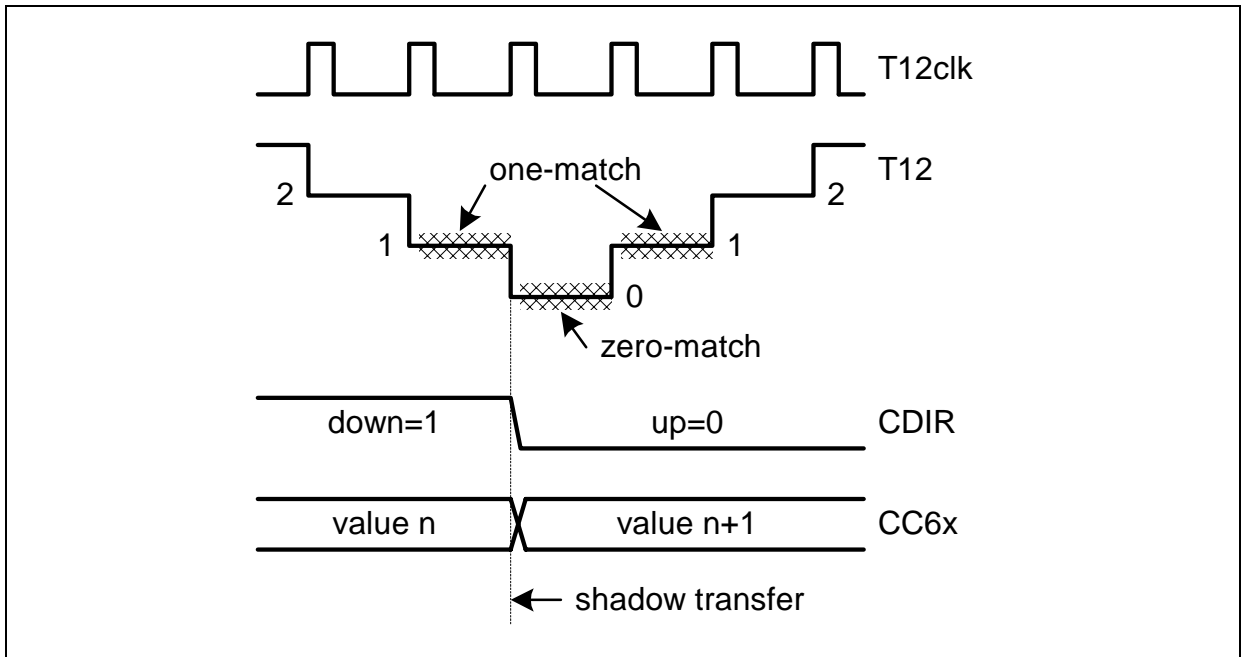

Figure 4-12 T12 in center-aligned mode, one-match detected

Figure 4-13 T12 in center-aligned mode, period-match detected

### 4.7.1.3 Switching Rules

The compare actions take place in parallel for the three compare channels. Depending on the count direction, the compare matches have different meanings. In order to get the PWM information independent from the output levels, two different states have been introduced for the compare actions: The active state and the passive state, which are used to generate the desired PWM as a combination of the states delivered by T13, the trap control unit and the multi-channel control unit. If the active state is interpreted as a '1' and the passive state as a '0', the state information is combined with a logical AND function.

- active AND active = active
- active AND passive = passive
- passive AND passive = passive

The compare states change with the detected compare-matches and are indicated by the CC6xST bits. The compare states of T12 are defined as follows:

- passive if the counter value is below the compare value
- active if the counter value is above the compare value

This leads to the following switching rules for the compare states:

- set to the active state when the counter value reaches the compare value while counting up
- reset to the passive state when the counter value reaches the compare value while counting down
- reset to the passive state in case of a zero-match without compare-match while counting up
- set to the active state in case of a zero-match with a parallel compare-match while counting up

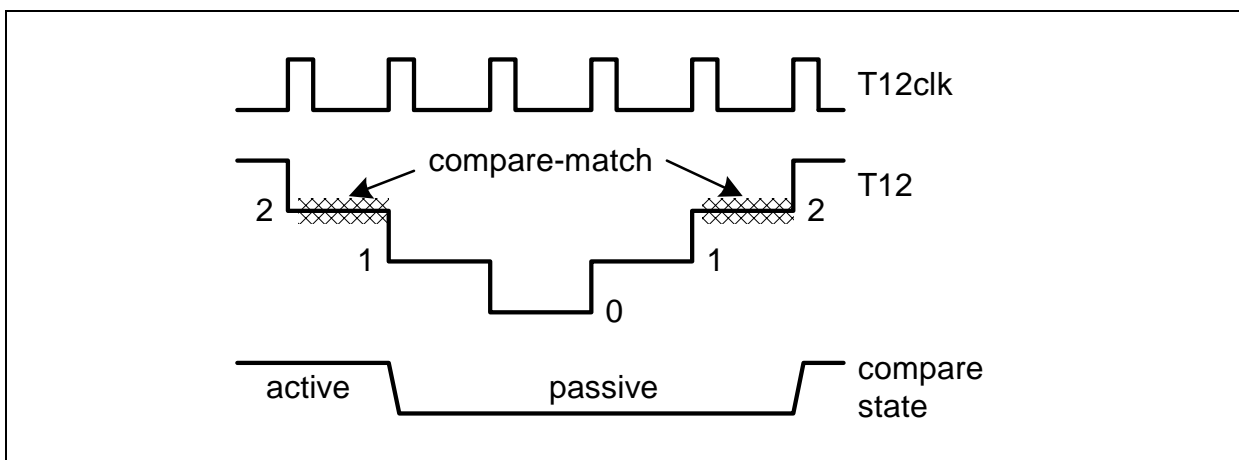

Figure 4-14 Compare States for Compare Value = 2

The switching rules are only taken into account while the timer is running. As a result, write actions to the timer registers while the timer is stopped do not lead to compare actions.

#### **4.7.1.4 Duty Cycle of 0% and 100%**

These counting and switching rules ensure a PWM functionality in the full range between 0% and 100% duty cycle (duty cycle = active time / total PWM period). In order to obtain a duty cycle of 0% (compare state never active), a compare value of T12P+1 has to be programmed (for both compare modes). A compare value of 0 will lead to a duty cycle of 100% (compare state always active).

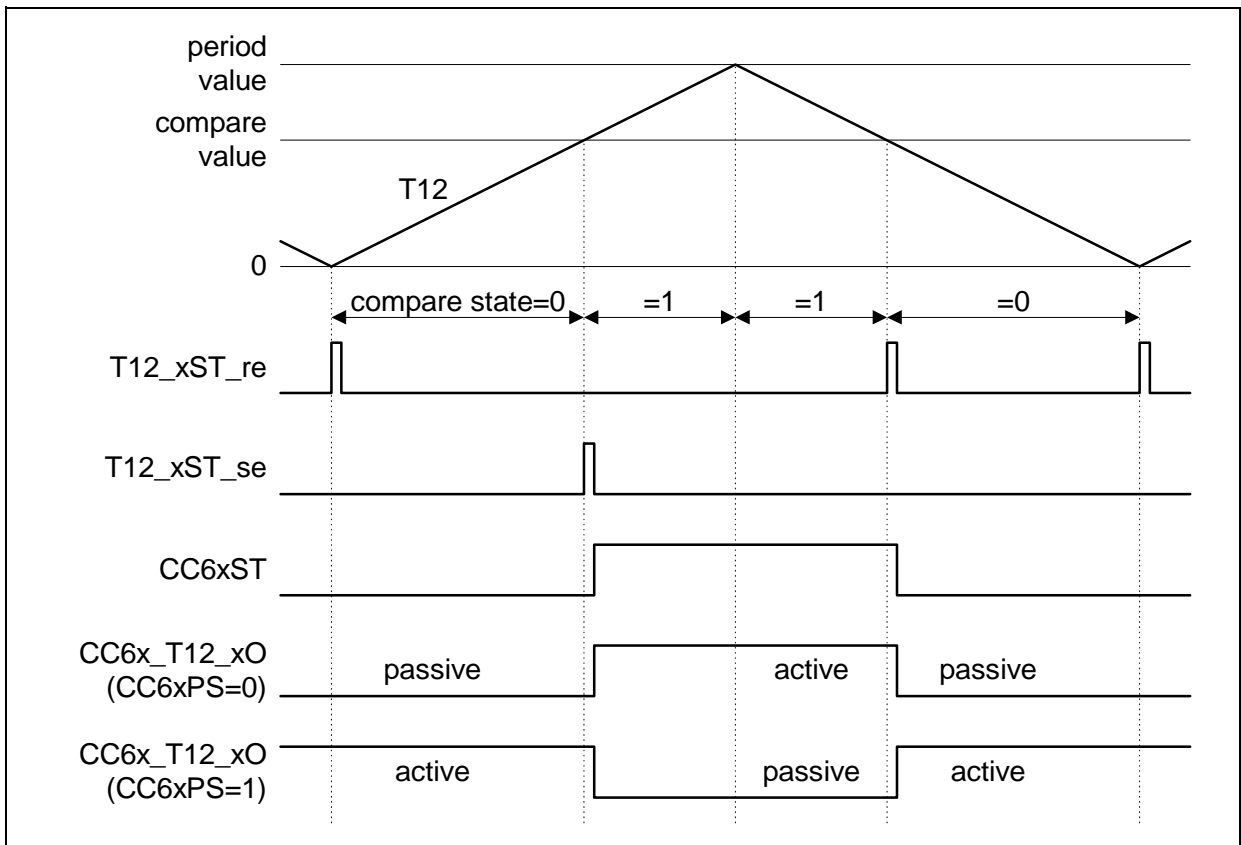

#### **4.7.1.5 Compare Mode of T12**

The following figure shows the setting and resetting of the compare state bit CC6xST. In order to simplify the description, only one out of the three parallel channels is described. The letter 'x' in the simplified bit names and signal names indicates that there are more than one channel. The CC6xST bit is the compare state bit in register CMPSTAT, the bit CC6xPS represents passive state select bit.

The timer T12 generates pulses indicating events like compare-matches, period-matches and zero-matches, which are used to set (signal T12\_xST\_se) and to reset (signal T12\_xST\_re) the corresponding compare state bit (CC6xST) according to the counting direction.

The timer T12 modulation output lines T12xO (two for each channel) can be selected to be in the active state while the corresponding compare state is '0' (with CC6xPS='0') or while the corresponding compare state is '1' (with CC6xPS='1'). The bit COUT6xPS has the same effect for the second output of the channel. The example is shown without dead-time.

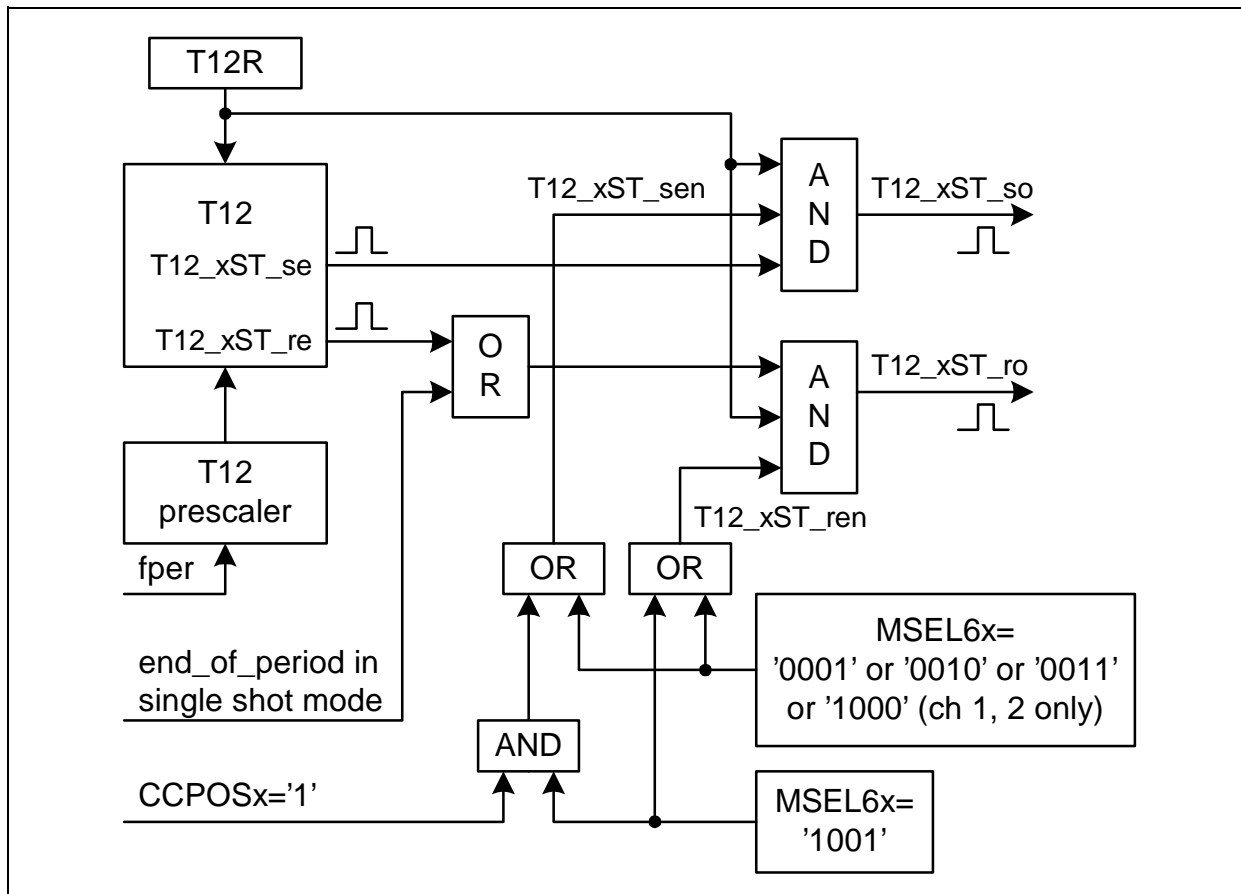

**Figure 4-15 Compare States of Timer T12**

According to the desired capture/compare mode, the compare state bits have to be switched. Therefore, an additional logic (see [Figure 4-16](#)) selects how and by which event the compare state bits are modified. The mode selection (by bitfields MSEL6x in register T12MSEL) enables the setting and the resetting of the compare state bits due to compare actions of timer T12.

The HW modifications of the compare state bits is only possible while the timer T12 is running. Therefore, the bit T12R is used to enable/disable the modification by HW.

For the hysteresis-like compare mode (MSEL6x='1001'), the setting of the compare state bit is only possible while the corresponding input CCPOSx='1' (inactive).

If the Hall Sensor mode (MSEL6x='1000') is selected, the compare state bits of the compare channels 1 and 2 are modified by the timer T12 in order to indicate that a programmed time has elapsed.

**Figure 4-16 T12 Compare Logic**

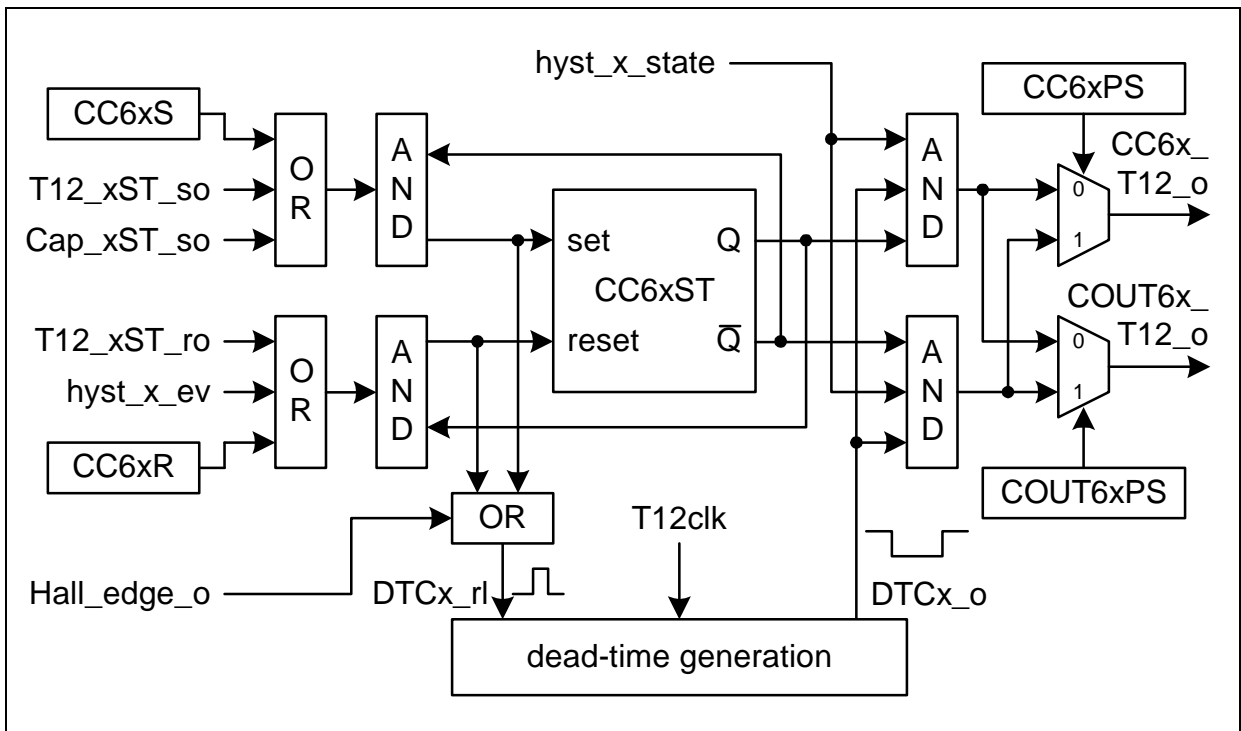

The T12 compare output lines T12\_xST\_so (to set bit CC6xST) and T12\_xST\_ro (to reset bit CC6xST) are also used to trigger the corresponding interrupt flags and to generate interrupts. The signal T12\_xST\_so indicates the interrupt event for the rising edge (ICC6xR), whereas the signal T12\_xST\_ro indicates the falling edge event (ICC6xF) in compare mode.

The compare state bits indicate the occurrence of a capture or compare event of the corresponding channel. It can be set (if it is '0') by the following events:

- upon a software set (CC6xS)
- upon a compare set event (see switching rules) if the T12 runs and if the T12 set event is enabled
- upon a capture set event

The bit CC6xST can be reset (if it is '1') by the following events:

- upon a software reset (CC6xR)
- upon a compare reset event (see switching rules) if the T12 runs and if the T12 reset event is enabled (including in single shot mode the end of the T12 period)
- upon a reset event in the hysteresis-like control mode

**Figure 4-17 T12 Logic for CC6xST Control**

The events triggering the set and reset action of the CC6xST bits have to be combined, see [Figure 4-17](#). The occurrence of the selected capture event (signal Cap\_xST\_so) or the setting of CC6xS in register CMPMODIF also leads to a set action of bit CC6xST, whereas the negative edge at pin CCPOSx (in hysteresis-like mode, signal hyst\_x\_ev) or the setting of bit CC6xR leads to reset action.

The set signal is only generated while bit CC6xST is reset, a reset can only take place while the bit is set. This permits the OR-combination of the resulting set and reset signals to one common signal (DTCx\_rl) triggering the reload of the dead-time counter. It is only triggered if bit CC6xST is changed, permitting a correct PWM generation with dead-time and the complete duty cycle range of 0% to 100% in edge-aligned and in center-aligned mode.

In the case that the dead-time generation is enabled, the change of bit CC6xST triggers the dead-time unit and a signal DTCx\_o is generated. The length of the '0' level of this signal corresponds to the desired dead-time, which is used to delay the rising edge (passive to active edge) of the output signal.

In order to generate independent PWM patterns for the highside and the lowside switches of the power inverter, the interval when a PWM signal should be active can be selected by the bits CC6xPS. They select if the PWM signal is active while the compare state bit is '0' (T12 counter value below the compare value) or while it is '1' (T12 counter value above the compare value).

In **Figure 4-17**, the signals CC6x\_T12\_o and COUT6x\_T12\_o are inputs to the modulation control block, where they can be combined with other PWM signals.

#### 4.7.1.6 Switching Examples in edge-aligned Mode

The following figure shows two switching examples in edge-aligned mode with duty cycles near to 0% and near to 100%. The compare-, period- or zero-matches lead to modifications of the compare state and the shadow transfer (if requested by STE12='1') in the next clock cycle.

**Figure 4-18** Switching Examples in edge-aligned Mode

#### 4.7.1.7 Switching Examples in center-aligned Mode

The following figures show examples of the switching of the compare state and the T12 shadow transfer according to the programmed compare values.

Figure 4-19 Switching Example for Duty Cycles near to 100%

Figure 4-20 Switching Example for Duty Cycles near to 0%

#### 4.7.1.8 Dead-time Generation

The generation of (complementary) signals for the highside and the lowside switches of one power inverter phase is based on the same compare channel. For example, if the

On-Chip Peripheral Components

highside switch should be active while the T12 counter value is above the compare value (compare state = '1'), then the lowside switch should be active while the counter value is below (compare state = '0'). The compare state, which may lead to an active output (respecting other modulation sources and the trap functionality) can be selected by the CC6xPS bits.

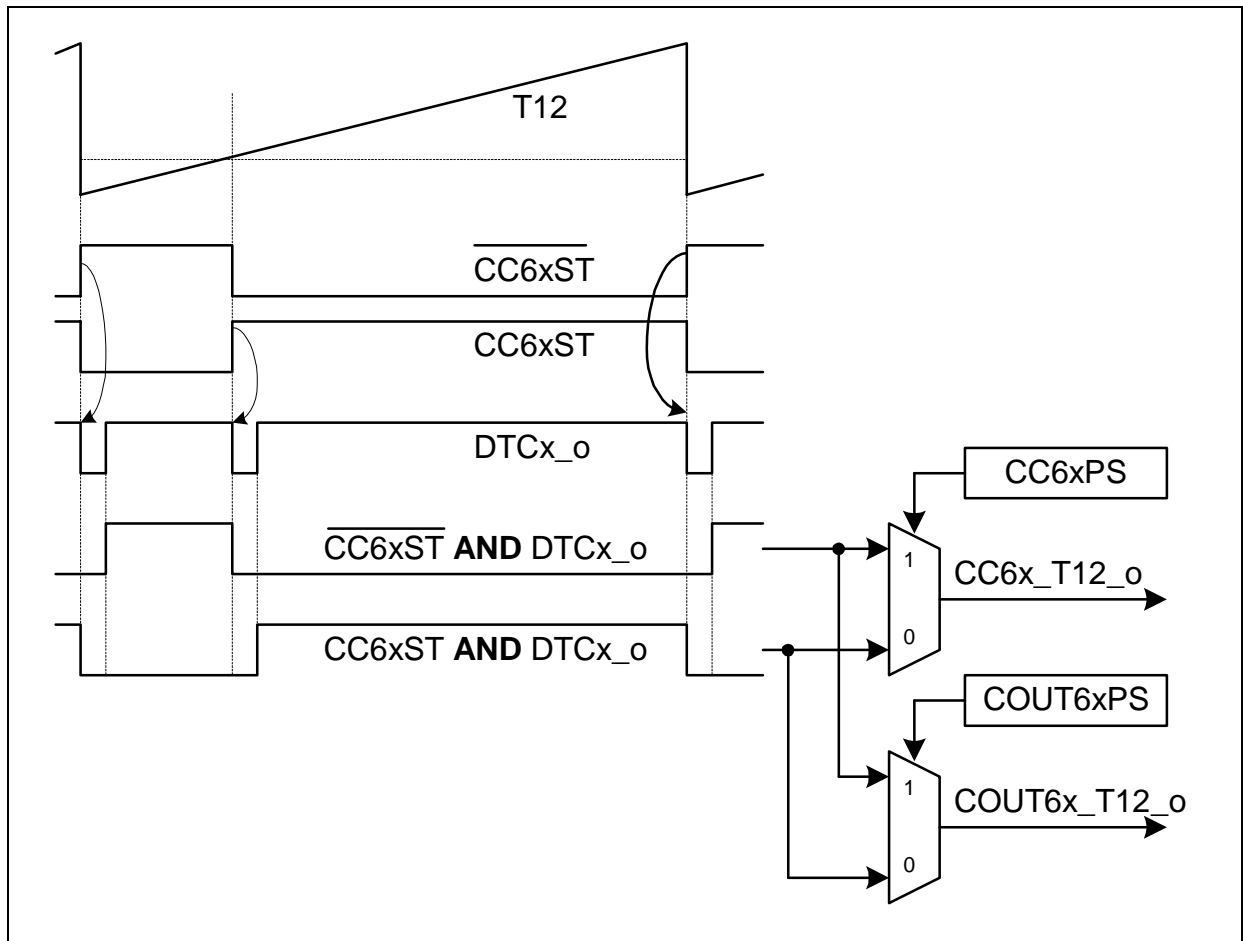

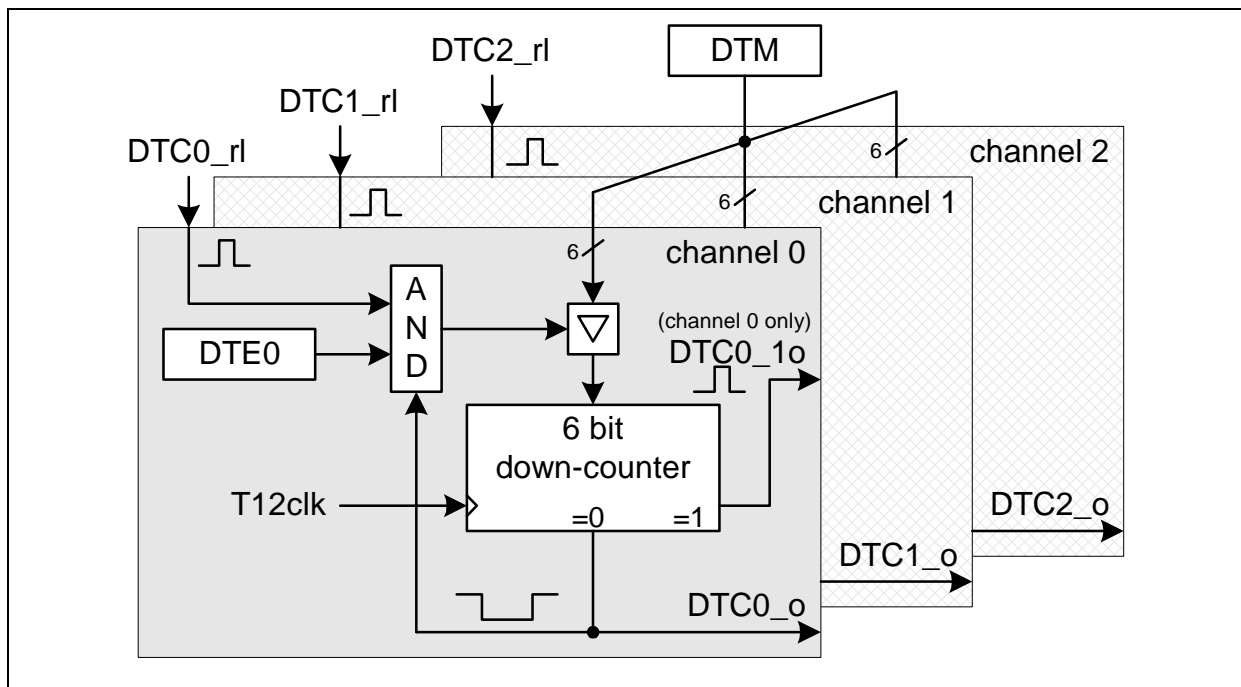

Figure 4-21 PWM-signals with Dead-time Generation

In most cases, the switching behavior of the connected power switches is not symmetrical concerning the times needed to switch on and to switch off. A general problem arises if the time to switch on is smaller than the time to switch off the power device. In this case, a short-circuit in the inverter bridge leg occurs, which may damage the complete system. In order to solve this problem by HW, this capture/compare unit contains a programmable dead-time counter, which delays the passive to active edge of the switching signals (the active to passive edge is not delayed), see [Figure 4-21](#).

The dead-time generation logic (see [Figure 4-22](#)) is built in a similar way for all three channels of T12. Each change of the CC6xST bits triggers the corresponding dead-time counter (6 bit down counter, clocked with T12clk). The trigger pulse (DTCx\_rl) leads to a reload of the dead-time counter with the value, which has been programmed in bit field

DTM. This reload can only take place if the dead-time feature is enabled by bit DTE<sub>x</sub> and while the counter is zero.

While counting down (zero is not yet reached), the output line DTC<sub>x</sub>\_o becomes '0'. This output line is combined with the T12 modulation signals, leading to a delay of the passive to active edge of the resulting signal, which is shown in [Figure 4-21](#). When reaching the counter value zero, the dead-time counter stops counting and the signal DTC<sub>x</sub>\_o becomes '1'. The dead-time counter can not be reloaded while it is counting.

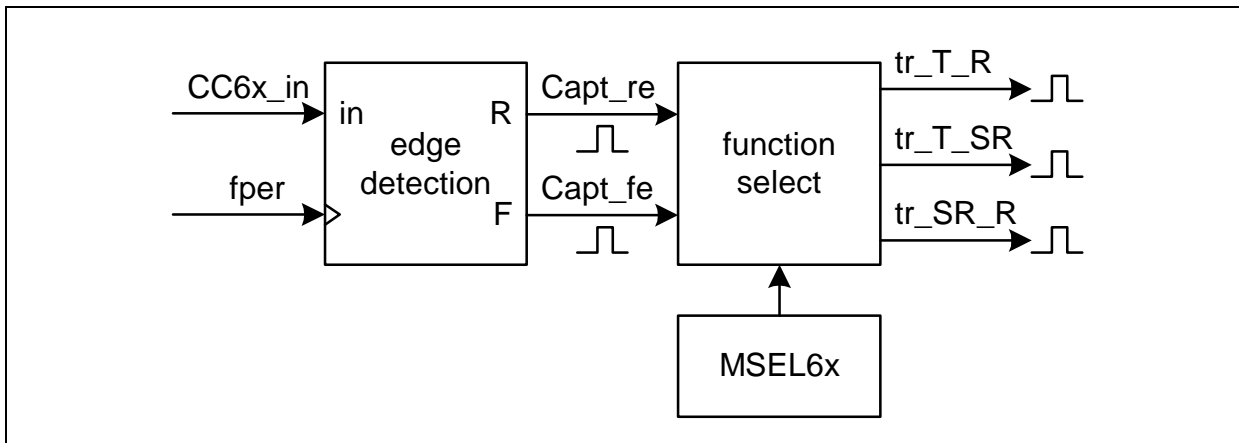

**Figure 4-22 Dead-time Counter**

Each of the three channels works independently with its own dead-time counter and the trigger and enable signals. The value of bit field DTM is valid for all of the three channels. In the Hall sensor mode, timer T12 is used to measure the rotational speed of the motor (channel 0 in capture mode) and to control the phase delay before switching to the next state (channel 1 in compare mode). Furthermore, channel 2 can be used to generate a time-out signal (in compare mode). As a result, T12 can not be used for modulation and, due to the block commutation patterns, a dead-time generation is not required. In order to built an efficient noise filter for the Hall signals, channel 0 of the dead-time unit is triggered (reloaded) with each detected edge of the Hall signals, see signal Hall\_edge\_o in [Figure 4-17](#). For this feature, channel 0 also generates a pulse if its counter value is one.

#### 4.7.1.9 Capture Mode

In capture mode the bits CC6<sub>x</sub>ST indicate the occurrence of the selected capture event according to the bit fields MSEL6<sub>x</sub>. A rising and/or a falling edge on the pins CC6<sub>x</sub> can

be selected as capture event, that is used to transfer the contents of timer T12 to the CC6xR and CC6xSR registers. In order to work in capture mode, the capture pins have to be configured as inputs.

**Figure 4-23 Capture Logic**

The block diagram of the capture logic for one channel is shown in **Figure 4-23**. This logic is identical for all three independent channels of timer T12. The input signal (CC6x\_in) from the input pin CC6x is connected to an edge detection logic delivering two output signals, one for the rising edge (Capt\_re) and one for the falling edge (Capt\_fe). These signals are also used as trigger sources for the channel interrupts if capture mode is selected.

There are several possibilities to store the captured values in the registers. In double register capture mode the timer value is stored in the channel shadow register CC6xSR. The value formerly stored in this register is simultaneously copied to the channel register CC6xR. This mode can be used if two capture events occur with very few time between them. The SW can then check the new captured value and has still the possibility to read the value captured before.

The selection of the capture mode is done by bitfield MSEL6x. According to the selected mode and the detected capture event, the signals tr\_T\_R (transfer T12 contents to register CC6xR), tr\_T\_SR (transfer T12 contents to register CC6xSR) or tr\_SR\_R (transfer contents of CC6xSR to register CC6xR) are activated.

*Note: In capture mode, a shadow transfer can be requested according to the shadow transfer rules, except for the capture / compare registers, that are left unchanged.*

#### 4.7.1.10 Single Shot Mode

In single shot mode, the timer T12 stops automatically at the end of the its counting period. **Figure 4-24** shows the functionality at the end of the timer period in edge-aligned

On-Chip Peripheral Components

and in center-aligned mode. If the end of period event is detected while bit T12SSC is set, the bits T12R and all CC6xST bits are reset.

Figure 4-24 End of Single Shot Mode of T12

### 4.7.1.11 Hysteresis-Like Control Mode

The hysteresis-like control mode (MSEL6x = '1001') offers the possibility to switch off the PWM output if the input CCPOSx becomes '0' by resetting bit CC6xST. This can be used as a simple motor control feature by using a comparator indicating e.g. over current. While CCPOSx='0', the PWM outputs of the corresponding channel are driving their passive levels. The setting of bit CC6xST is only possible while CCPOSx='1'.

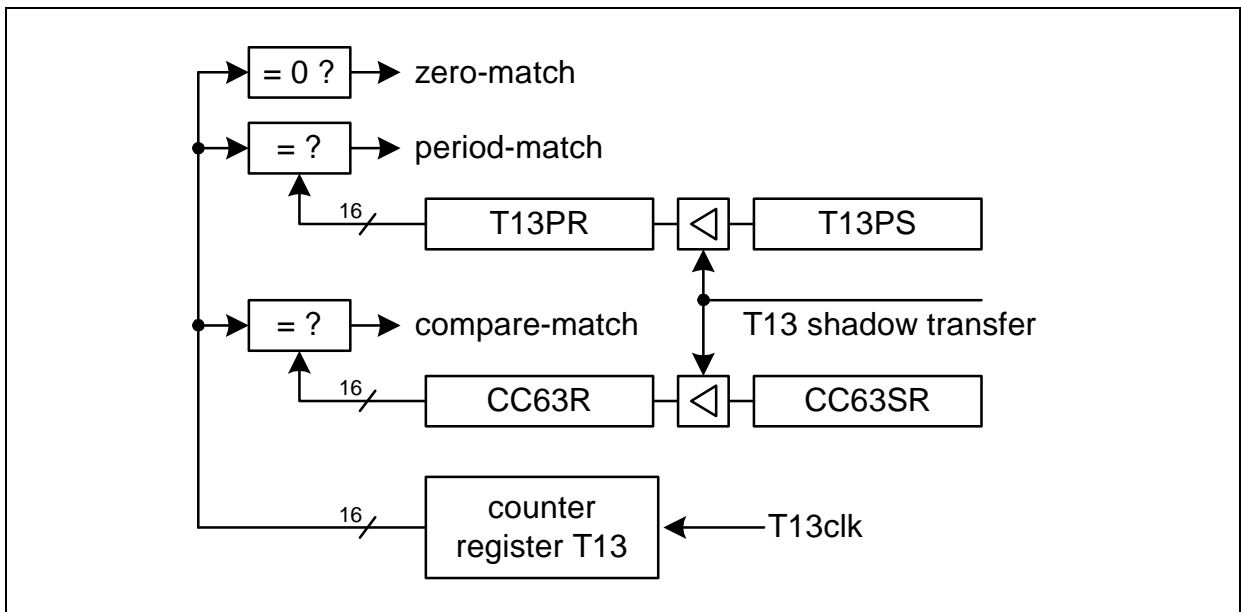

Figure 4-25 Hysteresis-Like Control Mode Logic

## 4.7.2 Timer T13

### 4.7.2.1 Overview

The timer T13 is built similar to T12, but only with one channel in compare mode. The counter can only count up (similar to the edge-aligned mode of T12). The T13 shadow transfer in case of a period-match is enabled by bit STE13 in register TCTR0. During the T13 shadow transfer, the contents of register CC63SR is transferred to register CC63R. Both registers can be read by SW, whereas only the shadow register can be written by SW.

The bits CC63PS, T13IM and PSL63 have shadow bits. The contents of the shadow bits is transferred to the actually used bits during the T13 shadow transfer. Write actions target the shadow bits, read actions deliver the value of the actually used bit.

**Figure 4-26 T13 Overview**

Timer T13 counts according to the same counting and switching rules as timer T12 in edge-aligned mode.

### 4.7.2.2 Compare Mode

The compare structure of T13 is based on the compare signals T13\_ST\_se (compare - match detected) and T13\_ST\_re (zero-match detected without compare-match). These compare signals may modify bit CC63ST only while the timer is running (T13R='1').

**Figure 4-27 T13 Compare Logic**

Similar to T12, bit CC63ST can be modified by SW by bits CC63S and CC63R. The output line COUT63\_T13\_o can generate a T13 PWM at the output pin COUT63. The signal MOD\_T13\_o can be used to modulate the other output signals with a T13 PWM. In order to decouple COUT63 from the internal modulation, the compare state leading to an active signal can be selected independently by bits T13IM and COUT63PS.

Figure 4-28 T13 Logic for CC6xST Control

#### 4.7.2.3 Single Shot Mode

The single shot mode of T13 is similar to the single shot mode of T12 in edge-aligned mode.

#### 4.7.2.4 Synchronization of T13 to T12

The timer T13 can be synchronized on a T12 event. The bit fields T13TEC and T13TED select the event, which is used to start timer T13. This event sets bit T13R per HW and T13 starts counting. Combined with the single shot mode, this feature can be used to generate a programmable delay after a T12 event.

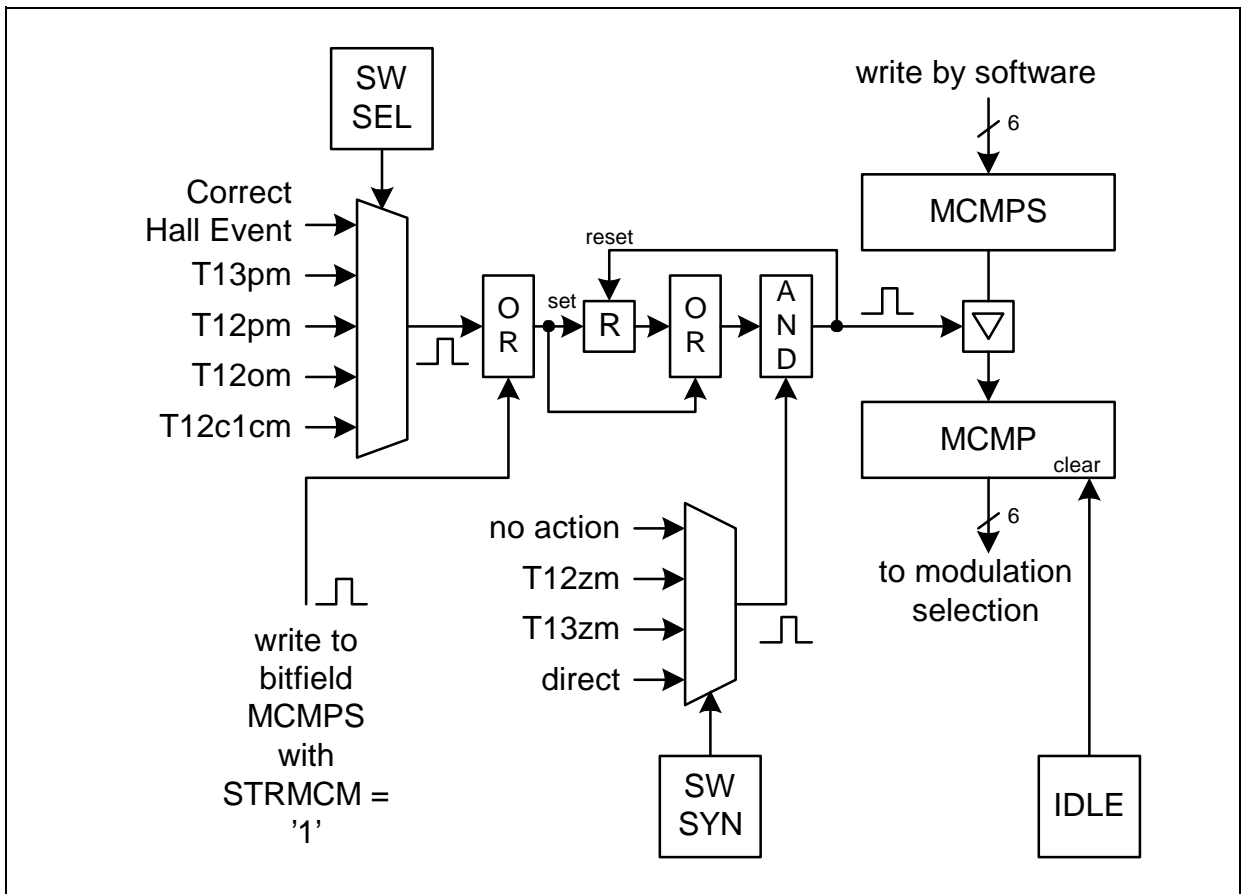

**Figure 4-29 Synchronization of T13 to T12**

This figure shows the synchronization of T13 to a T12 event. The selected event in this example is a compare-match (compare value = 2) while counting up. The clocks of T12 and T13 can be different (other prescaler factor), but for reasons of simplicity, this example shows the case for T12clk equal to T13clk.

### 4.7.3 Multi-channel Mode

The multi-channel mode offers a possibility to modulate all six T12-related output signals within one instruction. The bits in bit field MCMP are used to select the outputs that may become active. If the multi-channel mode is enabled (bit MCMEN='1'), only those outputs may become active, which have a '1' at the corresponding bit position in bit field MCMP.

This bit field has its own shadow bit field MCMPS, which can be written by SW. The transfer of the new value in MCMPS to the bit field MCMP can be triggered by and synchronized to T12 or T13 events. This structure permits the SW to write the new value, which is then taken into account by the HW at a well-defined moment and synchronized to a PWM period. This avoids unintended pulses due to unsynchronized modulation sources (T12, T13, SW).

**Figure 4-30 Modulation Selection and Synchronization**

**Figure 4-30** shows the modulation selection for the multi-channel mode. The event that triggers the update of bit field MCMP is chosen by SWSEL. If the selected switching event occurs, the reminder flag R is set. This flag monitors the update request and it is automatically reset when the update takes place. In order to synchronize the update of MCMP to a PWM generated by T12 or T13, bit field SWSYN allows the selection of the synchronization event, which leads to the transfer from MCMPS to MCMP. Due to this structure, an update takes place with a new PWM period.

If it is explicitly desired, the update takes place immediately with the setting of flag R when the direct synchronization mode is selected. The update can also be requested by SW by writing to bit field MCMPS with the shadow transfer request bit STRMCM set. If this bit is set during the write action to the register, the flag R is automatically set. By using the direct mode and bit STRMCM, the update takes place completely under SW control.

The possible HW request events are:

- a T12 period-match while counting up (T12pm)
- a T12 one-match while counting down (T12om)
- a T13 period-match (T13pm)

- a T12 compare-match of channel 1 (T12c1cm)
- a correct Hall event

The possible HW synchronization events are:

- a T12 zero-match while counting up (T12zm)
- a T13 zero-match (T13zm)
- 

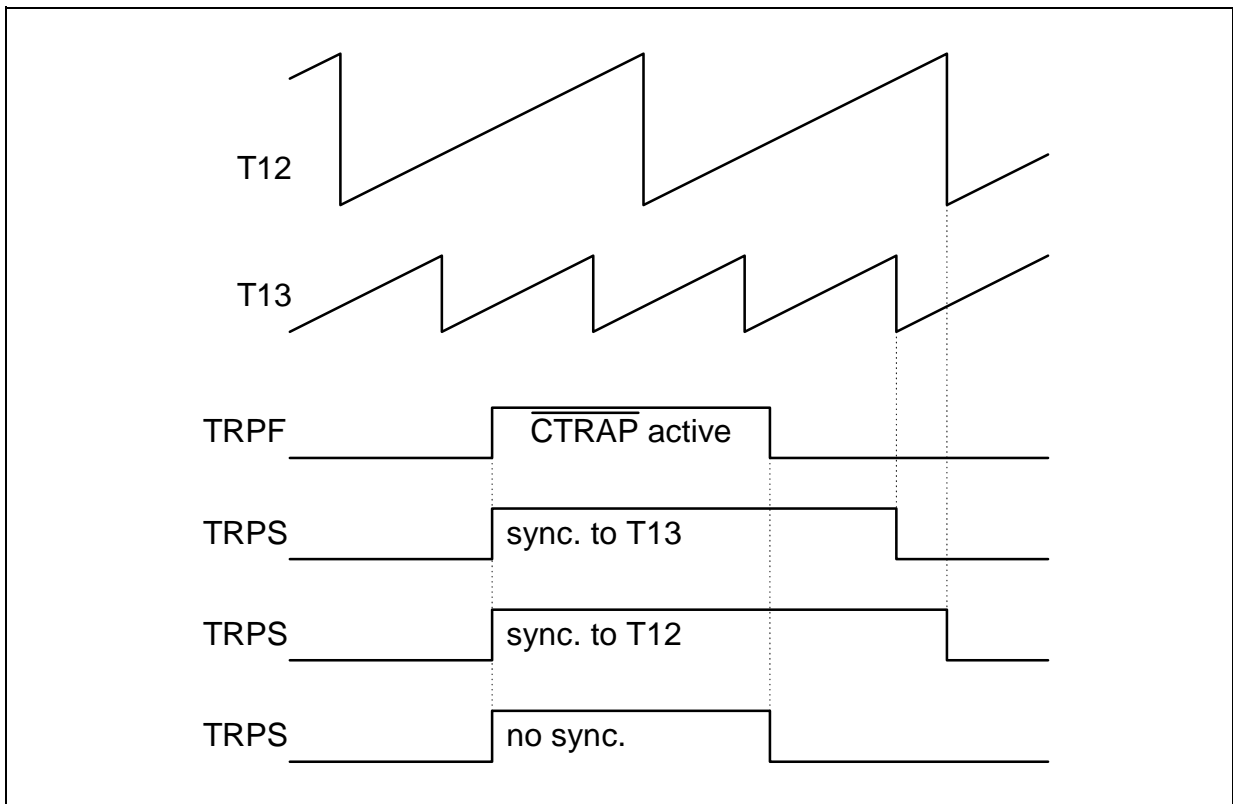

#### 4.7.4 Trap Handling

The trap functionality permits the PWM outputs to react on the state of the input pin CTRAP. This functionality can be used to switch off the power devices if the trap input becomes active (e.g. as emergency stop).

During the trap state, the selected outputs are forced to the passive state and no active modulation is possible. The trap state is entered immediately by HW if the CTRAP input signal becomes active and the trap function is enabled by bit TRPPEN. It can also be entered by SW by setting bit TRPF (trap input flag), leading to TRPS='1' (trap state indication flag). The trap state can be left when the input is inactive, by SW control and synchronized to the following events:

- TRPF is automatically reset after CTRAP becomes inactive (if TRPM2='0')
- TRPF has to be reset by SW after CTRAP becomes inactive (if TRPM2='1')
- synchronized to T12 PWM after TRPF is reset (T12 period-match in edge-aligned mode or one-match while counting down in center-aligned mode)
- synchronized to T13 PWM after TRPF is reset (T13 period-match)
- no synchronization to T12 or T13

**Figure 4-31 Trap State Synchronization (with TRM2='0')**

### 4.7.5 Modulation Control

The modulation control part combines the different modulation sources (CC6x\_T12\_o, COUT6x\_T12\_o = six T12-related signals from the three compare channels), the T13-related signal (MOD\_T13\_o) and the multi-channel modulation signals (MCMP bits). each modulation source can be individually enabled for each output line. Furthermore, the trap functionality is taken into account to disable the modulation of the corresponding output line during the trap state (if enabled).

**Figure 4-32 Modulation Control of T12-related Outputs**

The logic shown in [Figure 4-32](#) has to be built separately for each of the six T12-related output lines, referring to the index 'x' in the figure above.

The output level, that is driven while the output is in the passive state is defined by the corresponding bit in bit field PSL. If the resulting modulation signal is active, the inverted level of the PLSx bit is driven by the output stage.

The modulation control part for the T13-related output COUT63 combines the T13 output signal (COUT63\_T13\_o) and the enable bit ECT13O with the trap functionality. The output level of the passive state is selected by bit PSL63.

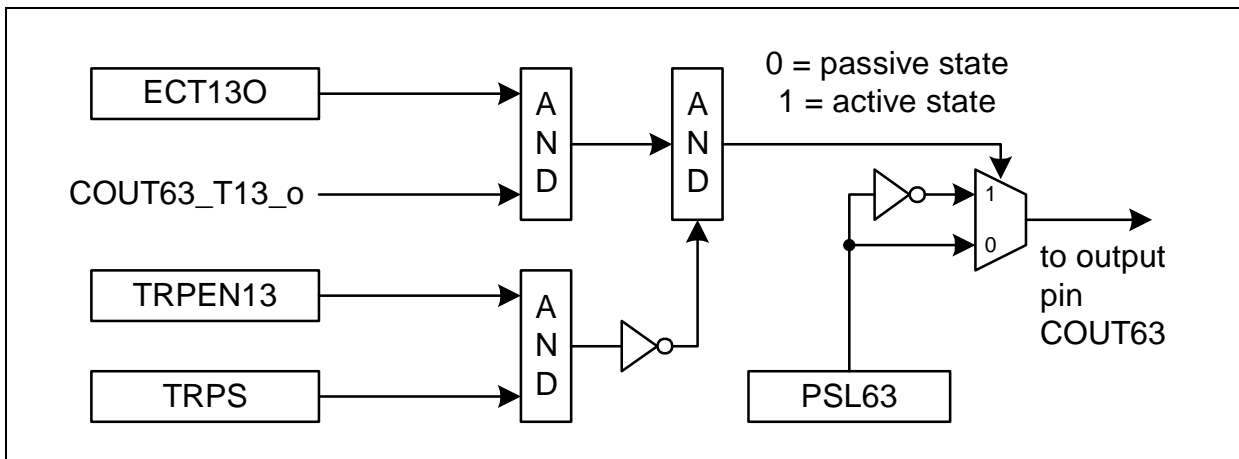

Figure 4-33 Modulation Control of the T13-related Output COU63

Note: In order to avoid spikes on the output lines, the seven output signals (CC60, COUT60, CC61, COUT61, CC62, COUT62, COUT63) are registered out with the peripheral clock.

#### 4.7.6 Hall Sensor Mode

In **Brushless-DC motors** the next multi-channel state values depend on the pattern of the Hall inputs. There is a strong correlation between the **Hall pattern** (CURH) and the **modulation pattern** (MCMP). Because of different machine types the modulation pattern for driving the motor can be different. Therefore it is wishful to have a wide flexibility in defining the correlation between the Hall pattern and the corresponding modulation pattern. The CCU6 offers this by having a register which contains the actual Hall pattern (CURHS), the next expected Hall pattern (EXPHS) and its output pattern (MCMPS). At every correct Hall event (CHE, see figure *Hall Event Actions*) a new Hall pattern with its corresponding output pattern can be loaded (from a predefined table) by software into the register MCMOUTS. Loading this shadow register can also be done by a write action on MCMOUTS with bit STRHP = '1'.

The **sampling** of the Hall pattern (on CCPOSx) is done with the T12 clock. By using the dead-time counter DTC0 (mode MSEL6x= '1000') a hardware **noise filter** can be implemented to suppress spikes on the Hall inputs due to high di/dt in rugged inverter environment. In case of a Hall event the DTC0 is reloaded and starts counting. When the counter value of one is reached, the CCPOSx inputs are sampled (without noise and spikes) and are compared to the current Hall pattern (CURH) and to the expected Hall pattern (EXPH). If the sampled pattern equals to the current pattern the edge on CCPOSx was due to a noise spike and no action will be triggered (implicit noise filter). If

On-Chip Peripheral Components

For **Brushless-DC** motors there is a special mode (MSEL6x = '1000b') which is triggered by a change of the Hall-inputs (CCPOSx). This mode shows the capabilities of the CCU6 (see also figures *Multi-channel Selection and Synchronization, Hall Event Actions, Modulation Selection and Alternate Output Enable of T12 and Timer T12 Brushless-DC Mode*). Here T12's channel 0 acts in capture function, channel 1 and 2 in compare function (without output modulation) and the multi-channel-block is used to trigger the output switching together with a possible modulation of T13.

After the detection of a valid Hall edge the T12 count value is captured to channel 0 (representing the actual motor speed) and resets the T12. When the timer reaches the compare value in channel 1, the next multi-channel state is switched by triggering the shadow transfer of bit field MCMP (if enabled in bit field SWEN). This trigger event can be combined with several conditions which are necessary to implement a noise filtering (correct Hall event) and to synchronize the next multi-channel state to the modulation sources (avoiding spikes on the output lines). This compare function of channel 1 can be used as a phase delay for the position input to the output switching which is necessary if a sensorless back-EMF technique is used instead of Hall sensors. The compare value in channel 2 can be used as a time-out trigger (interrupt) indicating that the motors destination speed is far below the desired value which can be caused by a abnormal load change. In this mode the modulation of T12 has to be disabled (T12MODENx = '0').

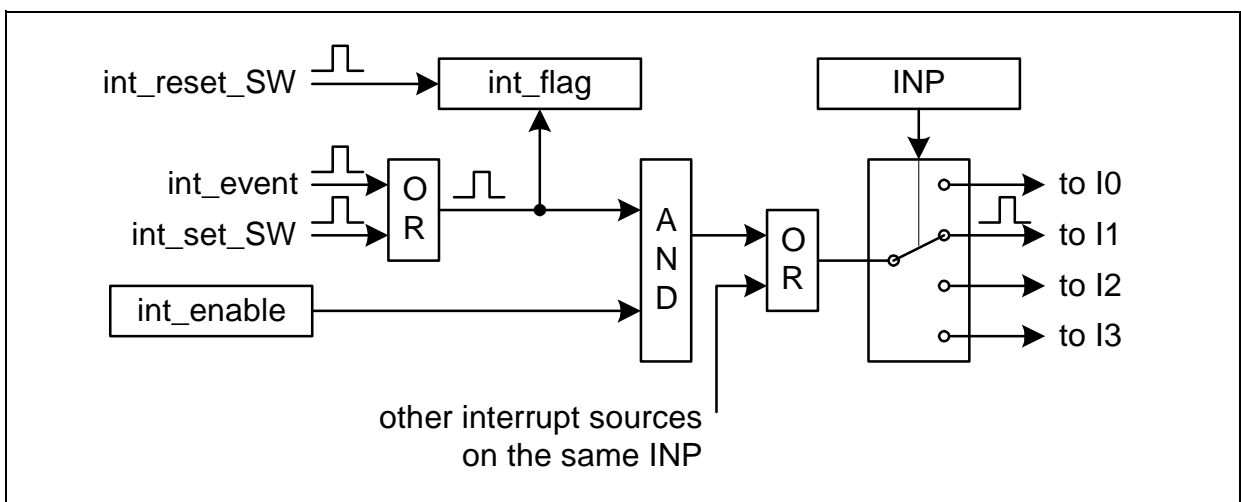

Figure 4-35 Timer T12 Brushless-DC Mode (MSEL6x = 1000)

### 4.7.7 Interrupt Generation

The interrupt structure is shown in [Figure 4-36](#). The interrupt event or the corresponding interrupt set bit (in register ISS) can trigger the interrupt generation. The interrupt pulse is generated independently from the interrupt flag in register IS. The interrupt flag can be reset by SW by writing to the corresponding bit in register ISR.

If enabled by the related interrupt enable bit in register IEN, an interrupt pulse can be generated at one of the four interrupt output lines of the module (length 2 clock cycles). If more than one interrupt source is connected to the same interrupt node pointer (in register INP), the requests are combined to one common line.

**Figure 4-36** Interrupt Generation

### 4.7.8 Module Powerdown

The CCU6 is disabled when the chip goes into the powerdown mode as describe in . Or it can be individually disabled by setting CCUDIS in register PMCON1. This helps to reduce current consumption in the normal, slow down and idle modes of operation if the CCU6 is not utilized. Bit CCUST in register PMCON2 reflects the powerdown status of CCU6.

## 4.8 Kernel Description

### 4.8.1 Register Overview

### 4.8.2 Timer12 - Related Registers

The generation of the patterns for a 3-channel pulse width modulation (PWM) is based on timer T12. The registers related to timer T12 can be concurrently updated (with well-defined conditions) in order to ensure consistency of the three PWM channels.

Timer T12 supports capture and compare modes, which can be independently selected for the three channels CC60, CC61 and CC62.

Register T12 represents the counting value of timer T12. It can only be written while the timer T12 is stopped. Write actions while T12 is running are not taken into account. Register T12 can always be read by SW.

In edge-aligned mode, T12 only counts up, whereas in center-aligned mode, T12 can count up and down.

#### T12L

Timer T12 Counter Register, Low Byte

[Reset value: 00<sub>H</sub>]

#### T12H

Timer T12 Counter Register, High Byte

[Reset value: 00<sub>H</sub>]

Field	Bits	Typ	Description
T12CV	[7:0] of T12 CVL, [7:0] of T12 CVH	rwh	<b>Timer 12 Counter Value</b> This register represents the 16-bit counter value of Timer12.

---

## On-Chip Peripheral Components

*Note: While timer T12 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.*

*Note: The timer period, compare values, passive state selects bits and passive levels bits for both timers are written to shadow registers and not directly to the actual registers. Thus the values for a new output signal can be programmed without disturbing the currently generated signal(s). The transfer from the shadow registers to the actual registers is enabled by setting the respective shadow transfer enable bit STEx.*

*If the transfer is enabled the shadow registers are copied to the respective registers as soon as the associated timer reaches the value zero the next time (being cleared in edge aligned mode or counting down from 1 in center aligned mode). When timer T12 is operating in center aligned mode, it will also copy the registers (if enabled by STE12) if it reaches the currently programmed period value (counting up).*

*When a timer is stopped (TxR='0'), the shadow transfer takes place immediately if the corresponding bit STEx is set.*

*After the transfer the respective bit STEx is cleared automatically.*

**On-Chip Peripheral Components**

Register T12PR contains the period value for timer T12. The period value is compared to the actual counter value of T12 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE12. A read action by SW delivers the value which is currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T12-related values.

**T12PRL**

**Timer T12 Period Register, Low Byte**

**[Reset value: 00<sub>H</sub>]**

**T12PRH**

**Timer T12 Period Register, High Byte**

**[Reset value: 00<sub>H</sub>]**

Field	Bits	Typ	Description
T12PV	[7:0] of T12 PRL, [7:0] of T12 PRH	rwh	<b>T12 Period Value</b> The value T12PV defines the counter value for T12, which leads to a period-match. When reaching this value, the timer T12 is set to zero (edge-aligned mode) or changes its count direction to down counting (center-aligned mode).

**On-Chip Peripheral Components**

In compare mode, the registers CC6xR (x=0,1,2) are the actual compare registers for T12. The values stored in CC6xR are compared (all three channels in parallel) to the counter value of T12. In capture mode, the current value of the T12 counter register is captured by registers CC6xR if the corresponding capture event is detected.

The registers CC6xR can only be read by SW, the modification of the value is done by a shadow register transfer from register CC6xSR. The corresponding shadow registers CC6xSR can be read and written by SW. In capture mode, the value of the T12 counter register can also be captured by registers CC6xSR if the selected capture event is detected (depending on the selected mode).

**On-Chip Peripheral Components**

Register T12DTC controls the dead-time generation for the timer T12 compare channels. Each channel can be independently enabled/disabled for dead-time generation. If enabled, the transition from passive state to active state is delayed by the value defined by bit field DTM. The dead-time counter can only be reloaded while it is zero.

<b>DTR</b>	[6:4]	rh	<p><b>Dead Time Run Indication Bits</b></p> <p>Bits DTR0..DTR2 indicate the status of the dead time generation for each compare channel (0, 1, 2) of timer T12.</p> <p>0The value of the corresponding dead time counter channel is 0.</p> <p>1The value of the corresponding dead time counter channel is not 0.</p>
-	7,3	r	<p><b>reserved;</b></p> <p>returns '0' if read; should be written with '0';</p>

*Note: The dead time counters are clocked with the same frequency as T12.  
 This structure allows symmetrical dead time generation in center-aligned and in edge-aligned PWM mode. A duty cycle of 50% leads to CC6x, COUT6x switched on for: 0.5 \* period - dead time.*

*Note: The dead-time counters are not reset by bit T12RES, but by bit DTRES.*

### 4.8.3 Timer13 - Related Registers

The generation of the patterns for a single channel pulse width modulation (PWM) is based on timer T13. The registers related to timer T13 can be concurrently updated (with well-defined conditions) in order to ensure consistency of the PWM signal. T13 can be synchronized to several timer T12 events.

Timer T13 only supports compare mode on its compare channel CC63.

Register T13 represents the counting value of timer T13. It can only be written while the timer T13 is stopped. Write actions while T13 is running are not taken into account.

Register T13 can always be read by SW.

Timer T13 only supports edge-aligned mode (counting up).

**On-Chip Peripheral Components**

Register TCTR2 controls the single-shot and the synchronization functionality of both timers T12 and T13. Both timers can run in single-shot mode. In this mode they stop their counting sequence automatically after one counting period with a count value of zero. The single-shot mode and the synchronization feature of T13 to T12 allows the generation of events with a programmable delay after well-defined PWM actions of T12. For example, this feature can be used to trigger AD conversions after a specified delay (to avoid problems due to switching noise) synchronously to a PWM event.

On-Chip Peripheral Components

Field	Bits	Type	Description
<b>T13TEC</b>	[4:2]	rw	<b>T13 Trigger Event Control</b> Bitfield T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to following combinations: 000 no action 001 set T13R on a T12 compare event on channel 0 010 set T13R on a T12 compare event on channel 1 011 set T13R on a T12 compare event on channel 2 100 set T13R on any T12 compare event (ch. 0, 1, 2) 101 set T13R upon a period-match of T12 110 set T13R upon a zero-match of T12 (while counting up) 111 set T13R on any hall state change
<b>T13TED<sup>1)</sup></b>	[6:5]	rw	<b>Timer T13 Trigger Event Direction</b> Bitfield T13TED delivers additional information to control the automatic set of bit T13R in the case that the trigger action defined by T13TEC is detected. 00 reserved, no action 01 while T12 is counting up 10 while T12 is counting down 11 independent on the count direction of T12
<b>0</b>	7	r	<b>reserved;</b> returns '0' if read; should be written with '0';

<sup>1)</sup> Example:

If the timer T13 is intended to start at any compare event on T12 (T13TEC='100') the trigger event direction can be programmed to

- counting up >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting up
- counting down >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting down
- independent from bit CDIR >> each T12 channel 0, 1, 2 compare match triggers T13R

The timer count direction is taken from the value of bit CDIR. As a result, if T12 is running in edge-aligned mode (counting up only), T13 can only be started automatically if bitfield T13TED='01' or '11'.

**On-Chip Peripheral Components**

Register TCTR4 allows the SW control of the run bits T12R and T13R by independent set and reset conditions. Furthermore, the timers can be reset (while running) and the bits STE12 and STE13 can be controlled by SW.

## 4.8.4 Modulation Control Registers

### 4.8.4.1 Global Module Control

Register MODCTR contains control bits enabling the modulation of the corresponding output signal by PWM pattern generated by the timers T12 and T13. Furthermore, the multi-channel mode can be enabled as additional modulation source for the output signals.

**On-Chip Peripheral Components**

The register TRPCTR controls the trap functionality. It contains independent enable bits for each output signal and control bits to select the behavior in case of a trap condition. The trap condition is a low level on the CTRAP input pin, which is monitored (inverted level) by bit TRPF (in register IS). While TRPF='1' (trap input active), the trap state bit TRPS (in register IS) is set to '1'.

**On-Chip Peripheral Components**

Register PSLR defines the passive state level driven by the output pins of the module. The passive state level is the value that is driven by the port pin during the passive state of the output. During the active state, the corresponding output pin drives the active state level, which is the inverted passive state level. The passive state level permits to adapt the driven output levels to the driver polarity (inverted, not inverted) of the connected power stage.

The interrupt status bits and the CC6xST bits have to be reset by SW.*

**Table 4-4 Description of the Double-Register Capture modes.**

**Description**

**Double-Register Capture modes**

0100The contents of T12 is stored in CC6nR after a rising edge and in CC6nSR after a falling edge on the input pin CC6n.

0101The value stored in CC6nSR is copied to CC6nR after a rising edge on the input pin CC6n. The actual timer value of T12 is simultaneously stored in the shadow register CC6nSR. This feature is useful for time measurements between consecutive rising edges on pins CC6n. COUT6n is IO.

0110The value stored in CC6nSR is copied to CC6nR after a falling edge on the input pin CC6n. The actual timer value of T12 is simultaneously stored in the shadow register CC6nSR. This feature is useful for time measurements between consecutive falling edges on pins CC6n. COUT6n is IO.

0111The value stored in CC6nSR is copied to CC6nR after any edge on the input pin CC6n. The actual timer value of T12 is simultaneously stored in the shadow register CC6nSR. This feature is useful for time measurements between consecutive edges on pins CC6n. COUT6n is IO.

**Table 4-5 Description of the Combined-T12 modes.**

**Description**

**Combined-T12 modes**

1000Hall Sensor mode:

Capture mode for channel 0, compare mode for channels 1 and 2. The contents of T12 is captured into CC60 at a valid hall event (which is a reference to the actual speed). CC61 can be used for a phase delay function between hall event and output switching. CC62 can act as a time-out trigger if the expected hall event comes too late. The value '1000' has to be programmed to MSEL0, MSEL1 and MSEL2 if the hall signals are used. In this mode, the contents of timer T12 is captured in CC60 and T12 is reset after the detection of a valid hall event. In order to avoid noise effects, the dead-time counter channel 0 is started after an edge has been detected at the hall inputs. When reaching the value of '000001', the hall inputs are sampled and the pattern comparison is done.

1001Hysteresis-like control mode with dead time generation:

The negative edge of the CCPOSx input signal is used to reset bit CC6nST. As a result, the output signals can be switched to passive state immediately and switch back to active state (with dead time) if the CCPOSx is high and the bit CC6nST is set by a compare event.

**Table 4-6 Description of the Multi-Input Capture modes.**

Description

## 4.9 Serial Interface

The serial port of the C868 is full duplex, meaning it can transmit and receive simultaneously. It is also receive-buffered, meaning it can commence reception of a second byte before a previously received byte has been read from the receive register (however, if the first byte still hasn't been read by the time reception of the second byte is complete, one of the bytes will be lost). The serial port receive and transmit registers are both accessed at special function register SBUF. Writing to SBUF loads the transmit register, and reading SBUF accesses a physically separate receive register.

The serial port can operate in 3 asynchronous modes. The baud rate clock for the serial port is derived from the oscillator frequency (mode 2) or generated either by timer 1 or by a dedicated baud rate generator (mode 1, 3). Mode 0 is reserved.

### Mode 1, 8-Bit UART, Variable Baud Rate:

In mode 1, ten bits are transmitted (through TxD) or received (through RxD). They are a start bit (0), 8 data bits (LSB first), and a stop bit (1). On receive, the stop bit goes into RB8 in special function register SCON. The baud rate is variable. (See section 4.9.2 for more detailed information)

### Mode 2, 9-Bit UART, Fixed Baud Rate:

11 bits are transmitted (through TxD) or received (through RxD): a start bit (0), 8 data bits (LSB first), a programmable 9th bit, and a stop bit (1). On transmit, the 9th data bit (TB8 in SCON) can be assigned to the value of 0 or 1. Or, for example, the parity bit (P, in the PSW) could be moved into TB8. On receive, the 9th data bit goes into RB8 in special function register SCON, while the stop bit is ignored. The baud rate is programmable to either 1/32 or 1/64 of the oscillator frequency. (See section 4.9.3 for more detailed information)

### Mode 3, 9-Bit UART, Variable Baud Rate:

11 bits are transmitted (through TxD) or received (through RxD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). In fact, mode 3 is the same as mode 2 in all respects except the baud rate. The baud rate in mode 3 is variable. (See section 4.9.3 for more detailed information)

In all modes, transmission is initiated by any instruction that uses SBUF as a destination register. Reception is initiated in the modes by the incoming start bit if REN = 1.

The serial interface also provides interrupt requests when transmission or reception of a frames have been completed. The corresponding interrupt request flags are TI or RI, resp. See chapter 7 of this user manual for more details about the interrupt structure. The interrupt request flags TI and RI can also be used for polling the serial interface, if the serial interrupt is not to be used (i.e. serial interrupt not enabled).

### Multiprocessor Communication

Modes 2 and 3 have a special provision for multiprocessor communications. In these modes, 9 data bits are received. The 9th one goes into RB8. Then comes a stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8 = 1. This feature is enabled by setting bit SM2 in SCON. A way to use this feature in multiprocessor systems is as follows.

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte which identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With SM2 = 1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data bytes that will be coming. The slaves that weren't being addressed leave their SM2s set and go on about their business, ignoring the incoming data bytes.

SM2 can be used in mode 1 to check the validity of the stop bit. In a mode 1 reception, if SM2 = 1, the receive interrupt will not be activated unless a valid stop bit is received.

### Serial Port Registers

The serial port control and status register is the special function register SCON. This register contains not only the mode selection bits, but also the 9th data bit for transmit and receive (TB8 and RB8), and the serial port interrupt bits (TI and RI).

SBUF is the receive and transmit buffer of serial interface. Writing to SBUF loads the transmit register and initiates transmission. Reading out SBUF accesses a physically separate receive register.

#### 4.9.1 Baud Rate Generation

There are several possibilities to generate the baud rate clock for the serial port depending on the mode in which it is operating.

For clarification, some terms regarding the difference between "baud rate clock" and "baud rate" should be mentioned. The serial interface requires a clock rate which is 16 times the baud rate for internal synchronization. Therefore, the baud rate generators have to provide a "baud rate clock" to the serial interface which - there divided by 16 - results in the actual "baud rate". However, all formulas given in the following section already include the factor and calculate the final baud rate. Further, the abbreviation  $f_{SYS}$  refers to the system frequency.

**On-Chip Peripheral Components**

The baud rate of the serial port is controlled by a bit which are located in the special function registers as shown below.

**PCON**

**Power Control Register**

[Reset value: 0XXX0000<sub>B</sub>]

7	6	5	4	3	2	1	0
<b>SMOD</b>	-	-	<b>SD</b>	<b>GF1</b>	<b>GF0</b>	<b>PDE</b>	<b>IDLE</b>
rw	r	r	rw	rw	rw	rw	rw

The functions of the shaded bits are not described here

Field	Bits	Typ	Description
SMOD	7	rw	<b>Double baud rate</b> When set, the baud rate of serial interface in modes 1, 2, 3 is doubled. After reset this bit is cleared.

Depending on the programmed operating mode different paths are selected for the baud rate clock generation.

**4.9.1.1 Baud Rate in Mode 2**

The baud rate in mode 2 depends on the value of bit SMOD in special function register PCON. If SMOD = 0 (which is the value after reset), the baud rate is 1/64 of the system frequency. If SMOD = 1, the baud rate is 1/32 of the system frequency.

$$\text{Mode 2 baud rate} = \frac{2^{\text{SMOD}}}{64} \times \text{system frequency}$$

**4.9.1.2 Baud Rate in Mode 1 and 3**

In these modes the baud rate is variable and can be generated alternatively by a baud rate generator or by timer 1.

**Using the Timer 2 as Baud Rate Generator**

In modes 1 and 3, the C868 can use timer 2 as the baud rate generator for the serial port. To enable the baud generator for transmit, bit TCLK (bit 4 of special function register

**On-Chip Peripheral Components**

T2CON) must be set. To enable the baud generator for receive, bit RCLK (bit 5 of special function register T2CON) must be set.

With the timer 2 as clock source for the serial port in mode 1 and 3, the baud rate can be determined as follows:

$$\text{Mode 1, 3 baud rate} = \frac{2^{\text{SMOD}}}{32} \times (\text{timer 2 overflow rate})$$

$$\text{Timer 2 overflow rate} = 2 \times (2^{16} - \text{RC2}) / \text{system frequency}$$

with RC2 = RC2H.7..0, RC2L.7..0 and timer2 count direction is set to up.

**Using Timer 2 to Generate Baud Rates**

In modes 1 and 3 of the serial interface timer 1 can also be used for generating baud rates. Then the baud rate is determined by the timer 1 overflow rate and the value of SMOD as follows:

$$\text{Mode 1, 3 baud rate} = \frac{2^{\text{SMOD}}}{32} \times (\text{timer 1 overflow rate})$$

The timer 1 interrupt is usually disabled in this application. Timer 1 itself can be configured for either "timer" or "counter" operation, and in any of its operating modes. In most typical applications, it is configured for "timer" operation in the auto-reload mode (high nibble of TMOD = 0010<sub>B</sub>). In this case the baud rate is given by the formula:

$$\text{Mode 1, 3 baud rate} = \frac{2^{\text{SMOD}} \times \text{system frequency}}{32 \times 12 \times (256 - (\text{TH1}))}$$

Very low baud rates can be achieved with timer 1 if leaving the timer 1 interrupt enabled, configuring the timer to run as 16-bit timer (high nibble of TMOD = 0001<sub>B</sub>), and using the timer 1 interrupt for a 16-bit software reload.

## 4.9.2 Details about Mode 1

Ten bits are transmitted (through TxD), or received (through RxD): a start bit (0), 8 data bits (LSB first), and a stop bit (1). On reception, the stop bit goes into RB8 in SCON. The baud rate is determined either by the timer 1 overflow rate or by the internal baud rate generator.

**Figure 4-37** shows a simplified functional diagram of the serial port in mode 1. The associated timings for transmit/receive are illustrated in **Figure 4-38**.

Transmission is initiated by an instruction that uses SBUF as a destination register. The "Write-to-SBUF" signal also loads a 1 into the 9th bit position of the transmit shift register and flags the TX control unit that a transmission is requested. Transmission starts at the next rollover in the divide-by-16 counter. (Thus, the bit times are synchronized to the divide-by-16 counter, not to the "Write-to-SBUF" signal).

The transmission begins with activation of  $\overline{\text{SEND}}$ , which puts the start bit at TxD. One bit time later, DATA is activated, which enables the output bit of the transmit shift register to TxD. The first shift pulse occurs one bit time after that.

As data bits shift out to the right, zeroes are clocked in from the left. When the MSB of the data byte is at the output position of the shift register, then the 1 that was initially loaded into the 9th position is just to the left of the MSB, and all positions to the left of that contain zeroes. This condition flags the TX control unit to do one last shift and then deactivate  $\overline{\text{SEND}}$  and set TI. This occurs at the 10th divide-by-16 rollover after "Write-to-SBUF".

Reception is initiated by a detected 1-to-0 transition at RxD. For this purpose RxD is sampled at a rate of 16 times whatever baud rate has been established. When a transition is detected, the divide-by-16 counter is immediately reset, and  $1\text{FF}_{\text{H}}$  is written into the input shift register, and reception of the rest of the frame will proceed.

The 16 states of the counter divide each bit time into 16ths. At the 7th, 8th and 9th counter states of each bit time, the bit detector samples the value of RxD. The value accepted is the value that was seen in at least 2 of the 3 samples. This is done for the noise rejection. If the value accepted during the first bit time is not 0, the receive circuits are reset and the unit goes back to looking for another 1-to-0 transition. This is to provide rejection or false start bits. If the start bit proves valid, it is shifted into the input shift register, and reception of the rest of the frame will proceed.

As data bits come in from the right, 1s shift out to the left. When the start bit arrives at the leftmost position in the shift register, (which in mode 1 is a 9-bit register), it flags the RX control block to do one last shift, load SBUF and RB8, and set RI. The signal to load SBUF and RB8, and to set RI, will be generated if, and only if, the following conditions are met at the time the final shift pulse is generated.

- 1) RI = 0, and
- 2) either SM2 = 0, or the received stop bit = 1

---

## On-Chip Peripheral Components

If one of these two conditions is not met, the received frame is irretrievably lost. If both conditions are met, the stop bit goes into RB8, the 8 data bit goes into SBUF, and RI is activated. At this time, whether the above conditions are met or not, the unit goes back to looking for a 1-to-0 transition in RxD.

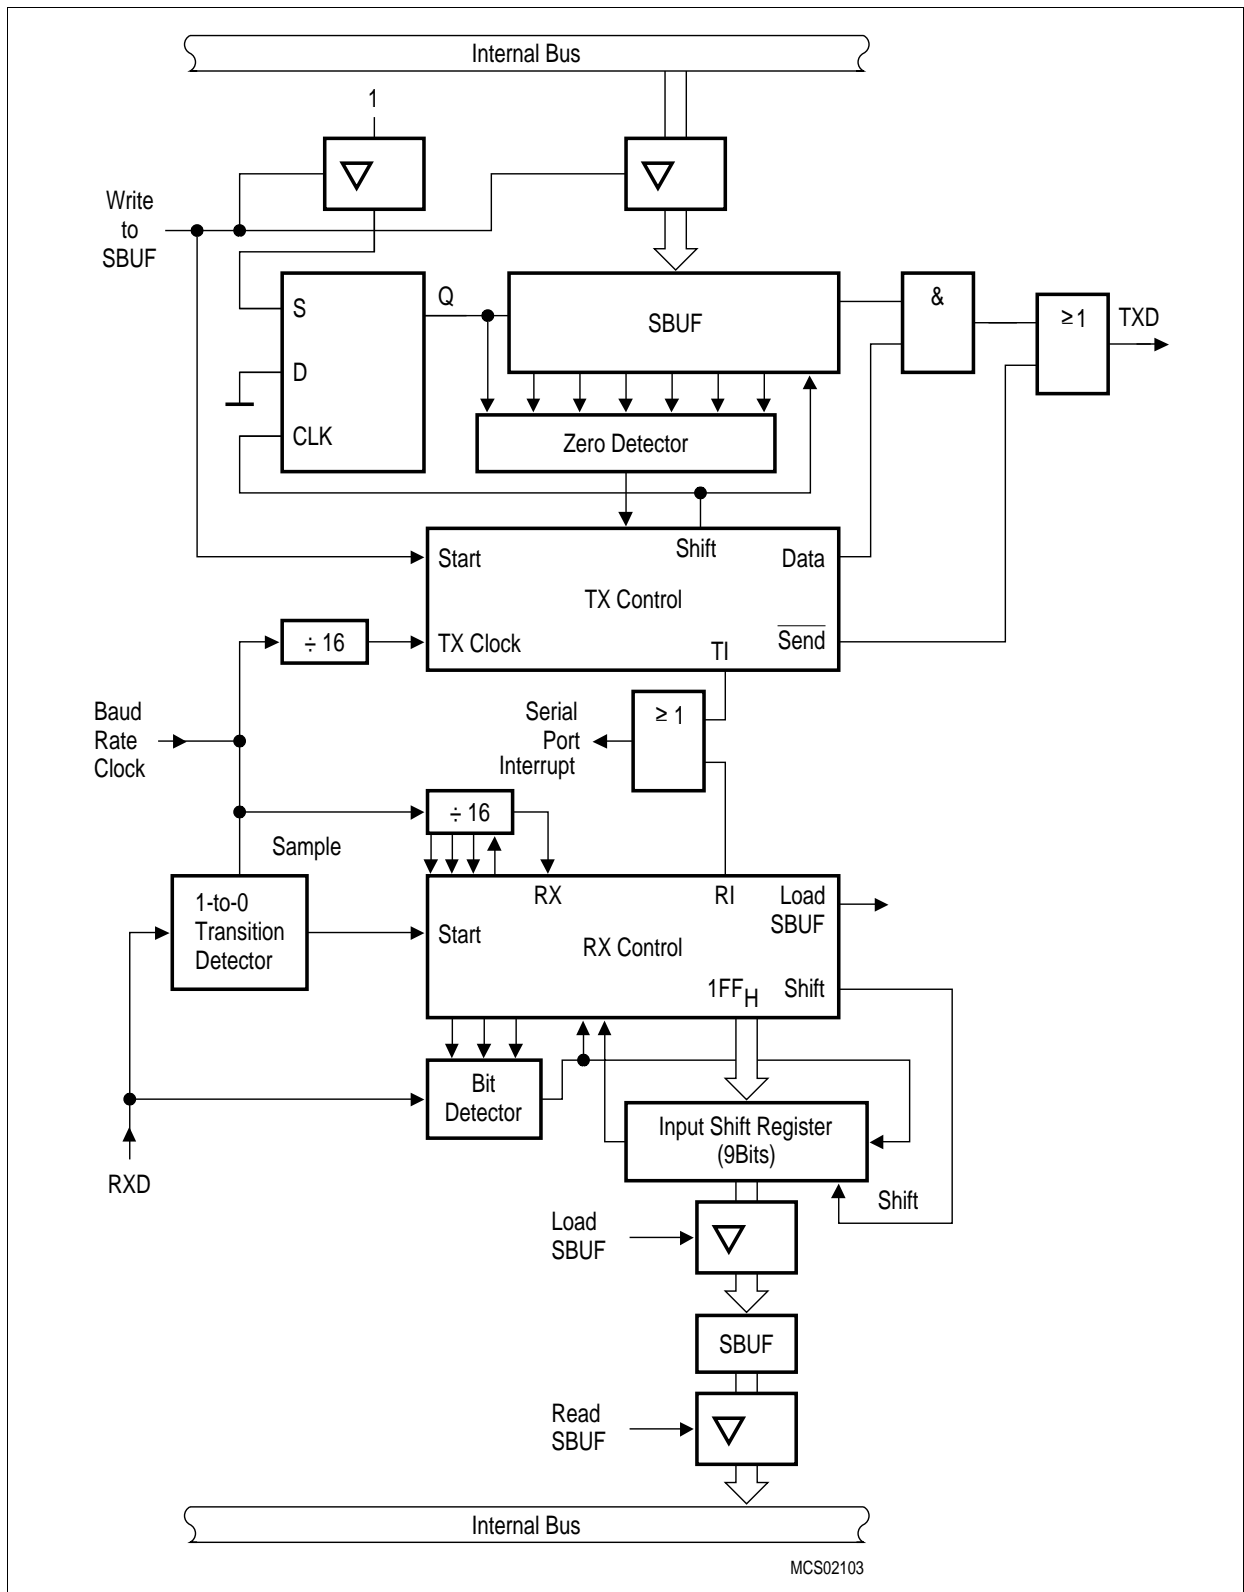

Figure 4-37 Serial Interface, Mode 1, Functional Diagram

**Figure 4-38 Serial Interface, Mode 1, Timing Diagram**

### 4.9.3 Details about Modes 2 and 3

Eleven bits are transmitted (through TxD), or received (through RxD): a start bit (0), 8 data bits (LSB first), a programmable 9th data bit, and a stop bit (1). On transmission, the 9th data bit (TB8) can be assigned the value of 0 or 1. On reception, the 9th data bit goes into RB8 in SCON. The baud rate is programmable to either 1/32 or 1/64 the system frequency in mode 2 (When bit SMOD in SFR PCON.7 is set, the baud rate is  $f_{SYS}/32$ ). In mode 3 the baud rate clock is generated by timer 1, which is incremented by a rate of  $f_{SYS}/12$  or by the internal baud rate generator.

**Figure 4-39** shows a functional diagram of the serial port in modes 2 and 3. The receive portion is exactly the same as in mode 1. The transmit portion differs from mode 1 only in the 9th bit of the transmit shift register. The associated timings for transmit/receive are illustrated in **Figure 4-40**.

Transmission is initiated by any instruction that uses SBUF as a destination register. The "Write-to-SBUF" signal also loads TB8 into the 9th bit position of the transmit shift register and flags the TX control unit that a transmission is requested. Transmission starts at the next rollover in the divide-by-16 counter. (Thus, the bit times are synchronized to the divide-by-16 counter, not to the "Write-to-SBUF" signal.)

The transmission begins with activation of SEND, which puts the start bit at TxD. One bit time later, DATA is activated, which enables the output bit of the transmit shift register to TxD. The first shift pulse occurs one bit time after that. The first shift clocks a 1 (the stop bit) into the 9th bit position of the shift register. Thereafter, only zeroes are clocked in. Thus, as data bits shift out to the right, zeroes are clocked in from the left. When TB8 is at the output position of the shift register, then the stop bit is just to the left of TB8, and all positions to the left of that contain zeroes. This condition flags the TX control unit to do one last shift and then deactivate SEND and set TI. This occurs at the 11th divide-by-16 rollover after "Write-to-SBUF".

Reception is initiated by a detected 1-to-0 transition at RxD. For this purpose RxD is sampled at a rate of 16 times whatever baud rate has been established. When a transition is detected, the divide-by-16 counter is immediately reset, and 1FF<sub>H</sub> is written to the input shift register.

At the 7th, 8th and 9th counter states of each bit time, the bit detector samples the value of RxD. The value accepted is the value that was seen in at least 2 of the 3 samples. If the value accepted during the first bit time is not 0, the receive circuits are reset and the unit goes back to looking for another 1-to-0 transition. If the start bit proves valid, it is shifted into the input shift register, and reception of the rest of the frame will proceed.

As data bit come from the right, 1s shift out to the left. When the start bit arrives at the leftmost position in the shift register (which in modes 2 and 3 is a 9-bit register), it flags the RX control block to do one last shift, load SBUF and RB8, and to set RI. The signal to load SBUF and RB8, and to set RI, will be generated if, and only if, the following conditions are met at the time the final shift pulse is generated:

---

**On-Chip Peripheral Components**

- 1)RI = 0, and
- 2)Either SM2 = 0 or the received 9th data bit = 1

If either of these conditions is not met, the received frame is irretrievably lost, and RI is not set. If both conditions are met, the received 9th data bit goes into RB8, and the first 8 data bit goes into SBUF. One bit time later, whether the above conditions were met or not, the unit goes back to looking for a 1-to-0 transition at the RxD input.

Note that the value of the received stop bit is irrelevant to SBUF, RB8 or RI.

## 4.10 A/D Converter

The C868 includes a high performance / high speed 8-bit A/D-Converter (ADC) with 5 analog input channels. It operates with a successive approximation technique and uses self calibration mechanisms for reduction and compensation of offset and linearity errors. The A/D converter provides the following features:

- 5 multiplexed input channels, which can also be used as digital inputs
- 8-bit resolution with TUE of +/- 2 LSB8.
- Single or continuous conversion mode
- Interrupt request generation after each conversion
- Using successive approximation conversion technique via a capacitor array
- Built-in calibration of offset and linearity errors
- Powerdown in normal, idle and slow-down modes

### 4.10.1 Register Definition of the ADC

The ADCON0 and ADCON1 registers are used to configure and control the ADC. It also indicates the status of the ADC functions (flags).

### 4.10.3 Operation of the ADC

The ADC supports two conversion modes - single and continuous conversions. For each mode, there are two ways in which conversion can be started - by software.

Writing a '1' to bit field ADST starts conversion on the channel that is specified by ADCH. In single conversion mode, bit field ADM is cleared to '0'. This is the default mode selected after hardware reset. When a conversion is started, the channel specified is sampled. The busy flag ADBSY is set and ADST is cleared. When the conversion is completed, the interrupt request is asserted and the 8-bit result is transferred to the result register ADDATH.

In continuous conversion mode, bit field ADM is set to '1'. In this mode, the ADC repeatedly converts the channel specified by ADCH. Bit ADST is cleared at the beginning of the first conversion. The busy flag ADBSY is asserted until the last conversion is completed. At the end of each conversion, the interrupt request will be asserted. To stop conversion, ADM has to be reset by software. If the channel number ADCH is changed while continuous conversion is in progress, the new channel specified will be sampled in the conversions that follow.

A new request to start conversion will be allowed only after the completion of any conversion that is in progress.

### 4.10.4 Module Powerdown

The ADC is disabled when the chip goes into the powerdown mode as describe in . Or it can be individually disabled by setting ADCDIS in register PMCON1. This helps to reduce current consumption in the normal, slow down and idle modes of operation if the ADC is not utilized. Bit ADCST in register PMCON2 reflects the powerdown status of ADC. If the ADC is disabled during an A/D conversion, ADC will be disabled (ADCST='1') only after the conversion is completed.

*Note :* Generally, before entering the power-down mode, an A/D conversion in progress must be stopped. If a single A/D conversion is running, it must be terminated by polling the ADBSY bit or waiting for the A/D conversion interrupt. In continuous conversion mode, ADM must be cleared and the last A/D conversion must be terminated before entering the power-down mode.

### 4.11 Conversion and Sample Time Control

The conversion and sample times are programmed via the bit fields ADCTC and ADSTC respectively of the register ADCON1. Bit field ADCTC (conversion time control) selects the internal ADC clock - `adc_clk`. Bit field ADSTC (sample time control) selects the sample time. The data in ADCTC and ADSTC can be modified while a conversion is in progress, but will only be evaluated after the current conversion has completed. Thus the change will only affect the subsequent conversion. The internal ADC clock, `adc_clk` is derived from the peripheral clock  $f_{SYS}$  according to :

$$adc\_clk = f_{SYS} / \text{clock divider}$$

Please note that the clock divider must be selected such that `adc_clk` does not exceed 2MHz.

The A/D conversion procedure is divided into four parts :

Synchronizing phase ( $t_{SYNC}$ ), delay before actual conversion commence.

Sample phase ( $t_S$ ), used for sampling the analog input voltage.

Conversion phase ( $t_{CO}$ ), used for the real A/D conversion (includes calibration).

Write result phase ( $t_{WR}$ ), used for writing the conversion result into the ADDAT registers.

The total A/D conversion time is defined by  $t_{ADCC}$  which is the sum of the four phase periods,  $t_{SYNC}$ ,  $t_S$ ,  $t_{CO}$  and  $t_{WR}$ .  $T_{ADCC}$  is computed with the following formula:

$$t_{ADCC} = 4/f_{SYS} + t_S + 8.5/adc\_clk$$

The sample time  $t_S$  is configured in periods of the selected internal ADC clock. The table below lists the possible combinations.

ADCTC	Clock Divider (TVC)	ADC Basic Clock <code>adc_clk</code>	ADSTC	Sample Time $t_S$ (Periods of <code>adc_clk</code> , STC)
00 (default)	32	$f_{SYS} / 32$	00 (default)	2
01	20	$f_{SYS} / 20$	01	4
10	16	$f_{SYS} / 16$	10	8
11	12	$f_{SYS} / 12$	11	16

**Sample Time  $t_S$  :**

During this time the internal capacitor array is connected to the selected analog input channel and is loaded with the analog voltage to be converted. The analog voltage is internally fed to a voltage comparator. With beginning of the sample phase the BSY bit in SFR ADCON0 is set.

**Conversion Time  $t_{CO}$  :**

During the conversion time the analog voltage is converted into a 8-bit digital value using the successive approximation technique with a binary-weighted capacitor network. During an A/D conversion also a calibration takes place. During this calibration alternating offset and linearity calibration cycles are executed. At the end of the calibration time the ADBSY bit is reset and the IADC bit in SFR IRCON1 is set indicating an A/D converter interrupt condition.

**Write Result Time  $t_{WR}$  :**

At the result phase the conversion result is written into the ADDATH registers.  
A/D Conversion Timing in Relation to Processor Cycles

Depending on the application, typically there are three methods to handle the A/D conversion in the C868.

Software delay

The machine cycles of the A/D conversion are counted and the program executes a software delay (e.g. NOPs) before reading the A/D conversion result in the write result cycle. This is the fastest method to get the result of an A/D conversion.

Polling ADBSY bit

The ADBSY bit is polled and the program waits until ADBSY=0. Attention : a polling JB instruction which is two machine cycles long, possibly may not recognize the ADBSY=0 condition during the write result cycle in the continuous conversion mode.

A/D conversion interrupt

After the start of an A/D conversion the A/D converter interrupt is enabled. The result of the A/D conversion is read in the interrupt service routine. If other C868 interrupts are enabled, the interrupt latency must be regarded. Therefore, this software method is the slowest method to get the result of an A/D conversion.

### 4.11.1 A/D Converter Calibration

The C868 A/D converter includes hidden internal calibration mechanisms which assure a safe functionality of the A/D converter according to the DC characteristics. The A/D converter calibration is implemented in a way that a user program which executes A/D conversions is not affected by its operation. Further, the user program has no control over the calibration mechanism. The calibration itself executes two basic functions :

Offset calibration : correction of offset errors of comparator and the capacitor network

Linearity calibration : correction of the binary-weighted capacitor network

The A/D converter calibration operates in two phases. First phase is the calibration after a reset operation and the second is the calibration at each A/D conversion. The calibration phases are controlled by a state machine in the A/D converter. This state machine executes the calibration phases and stores the calibration results dynamically in a small calibration RAM.

After a reset operation the A/D calibration is automatically started. This reset calibration phase, alternating offset and linearity calibration is executed. For achieving a proper reset calibration, the  $f_{ADC}$  prescaler value must satisfy the condition  $f_{ADC\ max} \leq 2\ MHz$ . If this condition is not met at a specific system frequency with the default prescaler value after reset, the  $f_{ADC}$  prescaler must be adjusted immediately after reset by setting bits ADCTC1 and ADCTC0 in SFR ADCON1 to a suitable value. It is also recommended to have the proper voltages, as specified in the DC specifications, applied at the  $V_{AREF}$  and  $V_{AGND}$  pins before the reset calibration has started.

After the reset calibration phase the A/D converter is calibrated according to its DC characteristics. Nevertheless, during the reset calibration phase single or continuous A/D can be executed. In this case it must be regarded that the reset calibration is interrupted and continued after the end of the A/D conversion. Therefore, interrupting the reset calibration phase by A/D conversions extends the total reset calibration time. If the specified total unadjusted error (TUE) has to be valid for an A/D conversion, it is recommended to start the first A/D conversions after reset when the reset calibration phase is finished. Depending on the system frequency selected, the reset calibration phase can be possibly shortened by setting ADCTC1 and ADCTC0 (prescaler value) to its final value immediately after reset.

After the reset calibration, a second calibration mechanism is initiated. This calibration is coupled to each A/D conversion. With this second calibration mechanism alternatively offset and linearity calibration values, stored in the calibration RAM, are always checked when an A/D conversion is executed and corrected if required.

## 5 Reset and System Clock Operation

### 5.1 Hardware Reset Operation

The hardware reset function incorporated in the C868 allows for an easy automatic start-up at a minimum of additional hardware and forces the controller to a predefined default state. The hardware reset function can also be used during normal operation in order to restart the device. This is particularly done when the power-down mode is to be terminated.

Additional to the hardware reset, which is applied externally to the C868, there are three internal reset sources, the watchdog timer, the brownout and the PLL. This chapter deals only with the external hardware reset and brownout.

The reset input is an active low input. An internal Schmitt trigger is used at the input for noise rejection. The  $\overline{\text{RESET}}$  pin must be held low for at least t<sub>bd</sub> usec. But the CPU will only exit from reset condition after the PLL lock had been detected.

During  $\overline{\text{RESET}}$  at transition from low to high, C868 will go into normal mode if ALE/BSL is high and bootstrap loading mode if ALE/BSL is low. A pullup to  $V_{\text{DDP}}$  is recommended for pin ALE/BSL. TXD should have a pullup to  $V_{\text{DDP}}$  and should not be stimulated externally during reset, as a logic low at this pin will cause the chip to go into test mode if ALE/BSL is low.

At the  $\overline{\text{RESET}}$  pin, a pullup resistor is connected to  $V_{\text{DDP}}$  and a capacitor is connected to ground to allow a power-up reset. After  $V_{\text{DDP}}$  has been turned on, the capacitor must hold the voltage level at the reset pin for a specific time to effect a complete reset.

## Reset and System Clock Operation

The time required for a reset operation must be at least tbd - tbd usec. The same considerations apply if the reset signal is generated externally (Figure 5-1 b). In each case it must be assured that the logics at ALE/BSL, TXD and other testmode related pins are latched properly.

**Figure 5-1 Reset Circuitries**

A correct reset leaves the processor in a defined state. The program execution starts at location 0000<sub>H</sub>. After reset is internally accomplished the port latches of ports 1 and 3 defaulted to FF<sub>H</sub>, and they are set to input.

The contents of the internal RAM and XRAM of the C868 are not affected by a reset. After power-up the contents are undefined, while it remains unchanged during a reset if the power supply is not turned off.

### 5.2 Internal Reset after Power-On

Figure 5-2 shows the power-on sequence.

For the C868, the device enter into default reset state once  $\overline{\text{RESET}}$  has gone low with all I/O ports set to input or high impedance. The internal reset is released only after the PLL has locked. In (Figure 5-2,II) the internal reset remains active even after the  $\overline{\text{RESET}}$  pin had gone high, the I/O ports 1 and 3 remain as input. In (Figure 5-2,III), detection for continuous PLL lock is done before internal reset is released. The 4096 cycles of continuous lock detection ensures that a reset due to PLL unlock will not happen during the transient period after the PLL started functioning. After continuous PLL lock is detected, the C868 starts operation.(Figure 5-2,IV)

Reset and System Clock Operation

Figure 5-2 Power-On Reset of the C868

Reset and System Clock Operation

5.3 Brownout

An on-chip analog circuit detects brownout, if the supply voltage  $V_{DDC}$  dips below the threshold voltage  $V_{THRESHOLD}$  momentarily while  $\overline{RESET}$  pin is high. If this detection is active for tbd usec then the device will reset. When supply voltage  $V_{DDC}$  recovers by exceeding  $V_{THRESHOLD}$  while  $\overline{RESET}$  is high, the reset is released once PLL is locked for 4096 clocks. Bit BO in the PMCON0 register is set when brownout detected if brownout detection was enabled, this bit is cleared by hardware reset  $\overline{RESET}$  and software. All ports are tristated during brownout.

The  $V_{THRESHOLD}$  has a nominal value of 1.47V, a minimum value of 1.1V and a maximum value of 1.8V.

## 5.4 Clock Generation

The top-level view of the system clock generation of the C868 is shown in [Figure 5-3](#).

**Figure 5-3 Block Diagram of the Clock Generation**

## 5.5 PLL Operation

The PLL consists of a voltage controlled oscillator (VCO) with a feedback path. A divider in the feedback path divides the VCO frequency down. The resulting frequency is then compared to the externally applied frequency. The phase detection logic determines the difference between the two clock signals and accordingly controls the frequency of the VCO. During start-up, the VCO increases its frequency until the divided feedback clock matches the external clock frequency. A lock detection logic monitors and signals this condition. The phase detection logic continues to monitor the two clock signals and adjusts the VCO clock if required.

The PLL provides mechanisms to detect a failure of the external clock and to bring the C868 into a safe state in such a case. When the PLL loses the lock to the external clock, either due to a break of the crystal or an external line, it generate an internal reset. The PLLR flag in the SCUWDT register is set, this flag can only be reset by a hardware reset or by software.

Due to this operation, the VCO clock of the PLL has a frequency which is a multiple of the externally applied clock. The factor for this is controlled through the value applied to the divider in the feedback path. That is why this factor is often called a multiplier, although it actually controls a divider. This parameter called the feedback divider has a fixed value  $N = 15$ .

When software power down mode is entered, the PLL is powered down.

### 5.5.1 VCO Frequency Ranges

The frequency range for  $f_{VCO}$  is:

$$100 \text{ MHz} \leq f_{VCO} \leq 160 \text{ MHz} \quad [5-1]$$

### 5.5.2 K-Divider

The K-Divider is a software controlled divider. The bit field KDIV is provided in register CMCON. Software can write to this field in order to change the PLL frequency  $f_{PLL}$ . The default KDIV value is 4. [Table 5-2](#) lists the possible values for KDIV and the resulting division factor.

The divider is designed such that a synchronous switching of the clock is performed without spurious or shortened clock pulses when software changes the divider factor KDIV. However, special attention has to be paid concerning the effect of such a clock change to the various modules in the system.

### 5.5.3 Determining the PLL Clock Frequency

This section gives the formulas for the determination of the PLL clock frequency. In PLL operation, the PLL clock is derived from the VCO frequency  $f_{VCO}$  divided by the K-factor.  $f_{VCO}$  is generated from the external clock multiplied by 15.

The PLL clock frequency  $f_{PLL}$  can be made proportional to the ratio 15 / K, where bit field CMCON.KDIV determines the clock scale factor K. The VCO output frequency is determined by:

$$f_{VCO} = 15 \cdot \Omega f_{OSC} \quad [5.2]$$

and the resulting PLL clock is determined by:

$$f_{PLL} = f_{VCO} / K = \frac{15}{K} \cdot \Omega f_{OSC} \quad [5.3]$$

Since stable operation of the VCO is only guaranteed if  $f_{VCO}$  remains inside of the defined frequency range for the VCO (see [Equation \[5-1\]](#)), the external frequency  $f_{OSC}$  is also confined to certain ranges. [Table 5-1](#) list the range.

**Table 5-1 Input Frequencies and N Factor=15 for  $f_{VCO}$**

$f_{VCO} = 100 \text{ MHz}$	$f_{VCO} = 160 \text{ MHz}$
6.67	10.67

**Table 5-2 Output Frequencies  $f_{PLL}$  Derived from Various Output Factors**

K-Factor		$f_{PLL}$		Duty Cycle [%]	Jitter
Selected Factor	KDIV	$f_{VCO} = 100 \text{ MHz}$	$f_{VCO} = 160 \text{ MHz}$		
2	000 <sub>B</sub>	50	80	50	linear depending on $f_{VCO}$ at $f_{VCO} = 100\text{MHz}$ : +/-300ps at $f_{VCO} = 160\text{MHz}$ : +/-250ps additional jitter for odd Kdiv factors tbd.
4	010 <sub>B</sub>	25	40	50	
5 <sup>1)</sup>	011 <sub>B</sub>	20	32	40	
6	100 <sub>B</sub>	16.67	26.67	50	
8	101 <sub>B</sub>	12.5	20	50	
9 <sup>1)</sup>	110 <sub>B</sub>	11.11	17.78	44	
10	111 <sub>B</sub>	10	16	50	
16	001 <sub>B</sub>	6.25	10	50	

1) These odd factors should not be used (not tested because off the unsymmetrical duty cycle).

2) Shaded combinations should not be used because they are above the maximum CPU frequency of 40MHz.

## 5.6 Slow Down Operation

The programmable Slow Down Divider (SDD) divides the PLL output clock frequency by a factor of 1...32 which is specified via CMCON.REL. When CMCON.REL is written during SDD operation the reload counter will output one more clock pulse with the 'old' frequency in order to synchronize it internally before generating the 'new' frequency.

**Figure 5-4 Slow Down Divider Operation**

$$SDD\_clk = PLL\_clk / (CMCON.REL_B + 1)$$

For a 20 MHz basic clock the on-chip logic may be run at a frequency down to 625 KHz without an external hardware change. During Slow Down operation the whole device (including bus interface) is clocked with the symmetrical SDD clock (see figure above).

### 5.6.1 Switching Between PLL Clock and SDD Clock

Switching Control logic controls the switching mechanism itself and ensures a continuous and glitch-free clock signal to the on-chip logic.

*Note: When switch from slow down mode to PLL operation (if configured), Master clock will be switched to PLL clock only after PLL (pll\_locked) is locked.*

Switching to Slow Down operation affects frequency sensitive peripherals like serial interfaces, timers, PWM, etc. If these units are to be operated in Slow Down mode their Prescalers or reload values must be adapted. Please note that the reduced CPU frequency decreases e.g. timer resolution and increases the step width e.g. for baudrate generation. The basic clock frequency in such a case should be chosen to accommodate the required resolutions and/or baudrates.

### 5.7 Oscillator and Clock Circuit

XTAL2 and XTAL1 are the input and output of a single-stage on-chip inverter which can be configured with off-chip components as a Pierce oscillator. The oscillator, in any case, drives the internal clock generator. The clock generator provides the internal clock signals to the chip. These signals define the internal phases, states and machine cycles.

**Figure 5-5** shows the recommended oscillator circuit.

**Figure 5-5 Recommended Oscillator Circuit**

In this application the on-chip oscillator is used as a crystal-controlled, positive-reactance oscillator (a more detailed schematic is given in **Figure 5-6**). It is operated in its fundamental response mode as an inductive reactor in parallel resonance with a capacitor external to the chip. The crystal specifications and capacitances are non-critical. In this circuit tbd pF can be used as single capacitance at any frequency together with a good quality crystal. A ceramic resonator can be used in place of the crystal in cost-critical applications. If a ceramic resonator is used, the two capacitors normally have different values depending on the oscillator frequency. We recommend consulting the manufacturer of the ceramic resonator for value specifications of these capacitors.

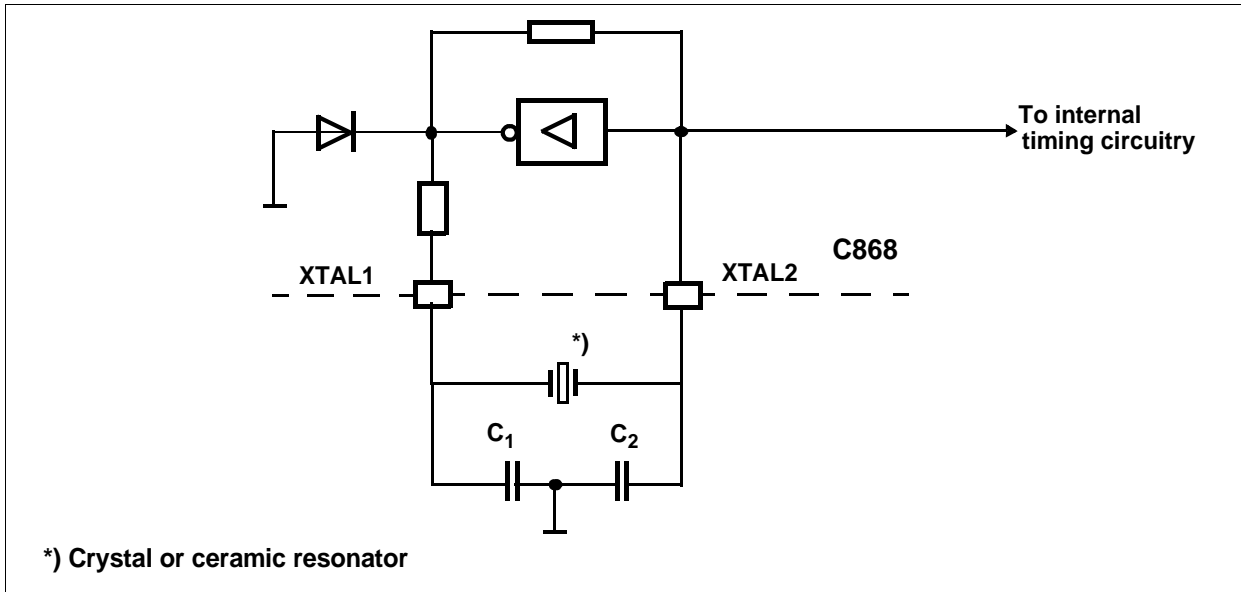

Figure 5-6 On-Chip Oscillator Circuitry

To drive the C868 with an external clock source, the external clock signal has to be applied to XTAL2, as shown in [Figure 5-7](#). XTAL1 has to be left unconnected. A pullup resistor is suggested (to increase the noise margin), but is optional if  $V_{OH}$  of the driving gate corresponds to the  $V_{IH2}$  specification of XTAL2.

Figure 5-7 External Clock Source

## 6 Fail Save Mechanism

The C868 offers enhanced fail save mechanisms, which allow an automatic recovery from software upset or hardware failure :

a programmable watchdog timer (WDT), with variable time-out period from 12.8 s to 819.2 s at  $f_{SYS} = 40$  MHz.

### 6.1 Programmable Watchdog Timer

To protect the system against software failure, the user’s program has to clear this watchdog within a previously programmed time period. If the software fails to do this periodical refresh of the watchdog timer, an internal reset will be initiated. The software can be designed so that the watchdog times out if the program does not work properly. It also times out if a software error is based on hardware-related problems.

The watchdog timer in the C868 is a 16-bit timer, which is incremented by a count rate of  $f_{SYS}/2$  upto  $f_{SYS}/128$ . The machine clock of the C868 is divided by a prescaler, a divide-by-two or a divide-by-128 prescaler. The upper 8 bits of the Watchdog Timer can be preset to a user-programmable value via a watchdog service access in order to vary the watchdog expire time. The lower 8 bits are reset on each service access. **Figure 6-1** shows the block diagram of the watchdog timer unit.

Figure 6-1 Block Diagram of the Programmable Watchdog Timer

#### 6.1.1 Register Definition of the Watchdog Timer

The current count value of the Watchdog Timer is contained in the Watchdog Timer Register WDT, which is a non-bitaddressable read-only register. The operation of the Watchdog Timer is controlled by its bitaddressable Watchdog Timer Control Register

### 6.1.2 Starting the Watchdog Timer

When the reset input to the Watchdog Timer, the Watchdog Timer is enabled. Once disabled it cannot be stopped during active mode of the device. If the software fails to clear the watchdog timer an internal reset will be initiated. The reset cause (external reset or reset caused by the watchdog) can be examined by software (status flag WDTR in SCUWDT is set). A refresh of the watchdog timer is done by setting bits WDTRE and WDTRS (in SFR SCUWDT) consecutively. This double instruction sequence has been implemented to increase system security.

It must be noted, however, that the watchdog timer is halted during the idle mode and power-down mode of the processor (see section "Power Saving Modes"). It is not possible to use the idle mode in combination with the watchdog timer function. Therefore, even the watchdog timer cannot reset the device when one of the power saving modes has been entered accidentally.

### 6.1.3 Refreshing the Watchdog Timer

At the same time the watchdog timer is started, the 8-bit register WDTRE is preset by the contents of WDTREL. Once started the watchdog cannot be stopped by software but can only be refreshed to the reload value by first setting bit WDTRE and WDTRS (in SFR SCUWDT) consecutively. Bit WDTR will automatically be cleared during the second machine cycle after having been set. For this reason, setting WDTRS bit has to be a one cycle instruction (e.g. SETB WDTRS). This double-instruction refresh of the watchdog timer is implemented to minimize the chance of an unintentional reset of the watchdog.

The reload register WDTREL can be written to at any time, as already mentioned. Therefore, a periodical refresh of WDTREL can be added to the above mentioned starting procedure of the watchdog timer. Thus a wrong reload value caused by a possible distortion during the write operation to the WDTREL can be corrected by software.

### 6.1.4 Input Clock Selection

The time period for an overflow of the Watchdog Timer is programmable in two ways :

- **the input frequency** to the Watchdog Timer can be selected via bit WDTIN in register WDTCON to be either  $f_{SYS}/2$  or  $f_{SYS}/128$ .
- **the reload value** WDTREL for the high byte of WDT can be programmed in register WDTCON.

The period  $P_{WDT}$  between servicing the Watchdog Timer and the next overflow can therefore be determined by the following formula:

[6.1]

$$P_{WDT} = \frac{2^{(1+WDTIN*6)} * (2^{16} - WDTREL * 2^8)}{f_{SYS}}$$

**Table 6-1** lists the possible ranges for the watchdog time which can be achieved using a certain module clock. Some numbers are rounded to 3 significant digits.

**Table 6-1 Watchdog Time Ranges**

Reload value in WDTREL	Prescaler for $f_{SYS}$					
	2 (WDTIN = '0')			128 (WDTIN = '1')		
	40 MHz	20 MHz	16 MHz	40 MHz	20 MHz	16 MHz
FF <sub>H</sub>	12.8 μs	25.6 μs	32.0 μs	819.2 μs	1.64 ms	2.05 ms
7F <sub>H</sub>	1.65 ms	3.3 ms	4.13 ms	105.7 ms	211.3 ms	264 ms
00 <sub>H</sub>	3.28 ms	6.55 ms	8.19 ms	209.7 ms	419.4 ms	524 ms

*Note : For safety reasons, the user is advised to rewrite WDTCON each time before the Watchdog Timer is serviced.*

## 7 Interrupt System

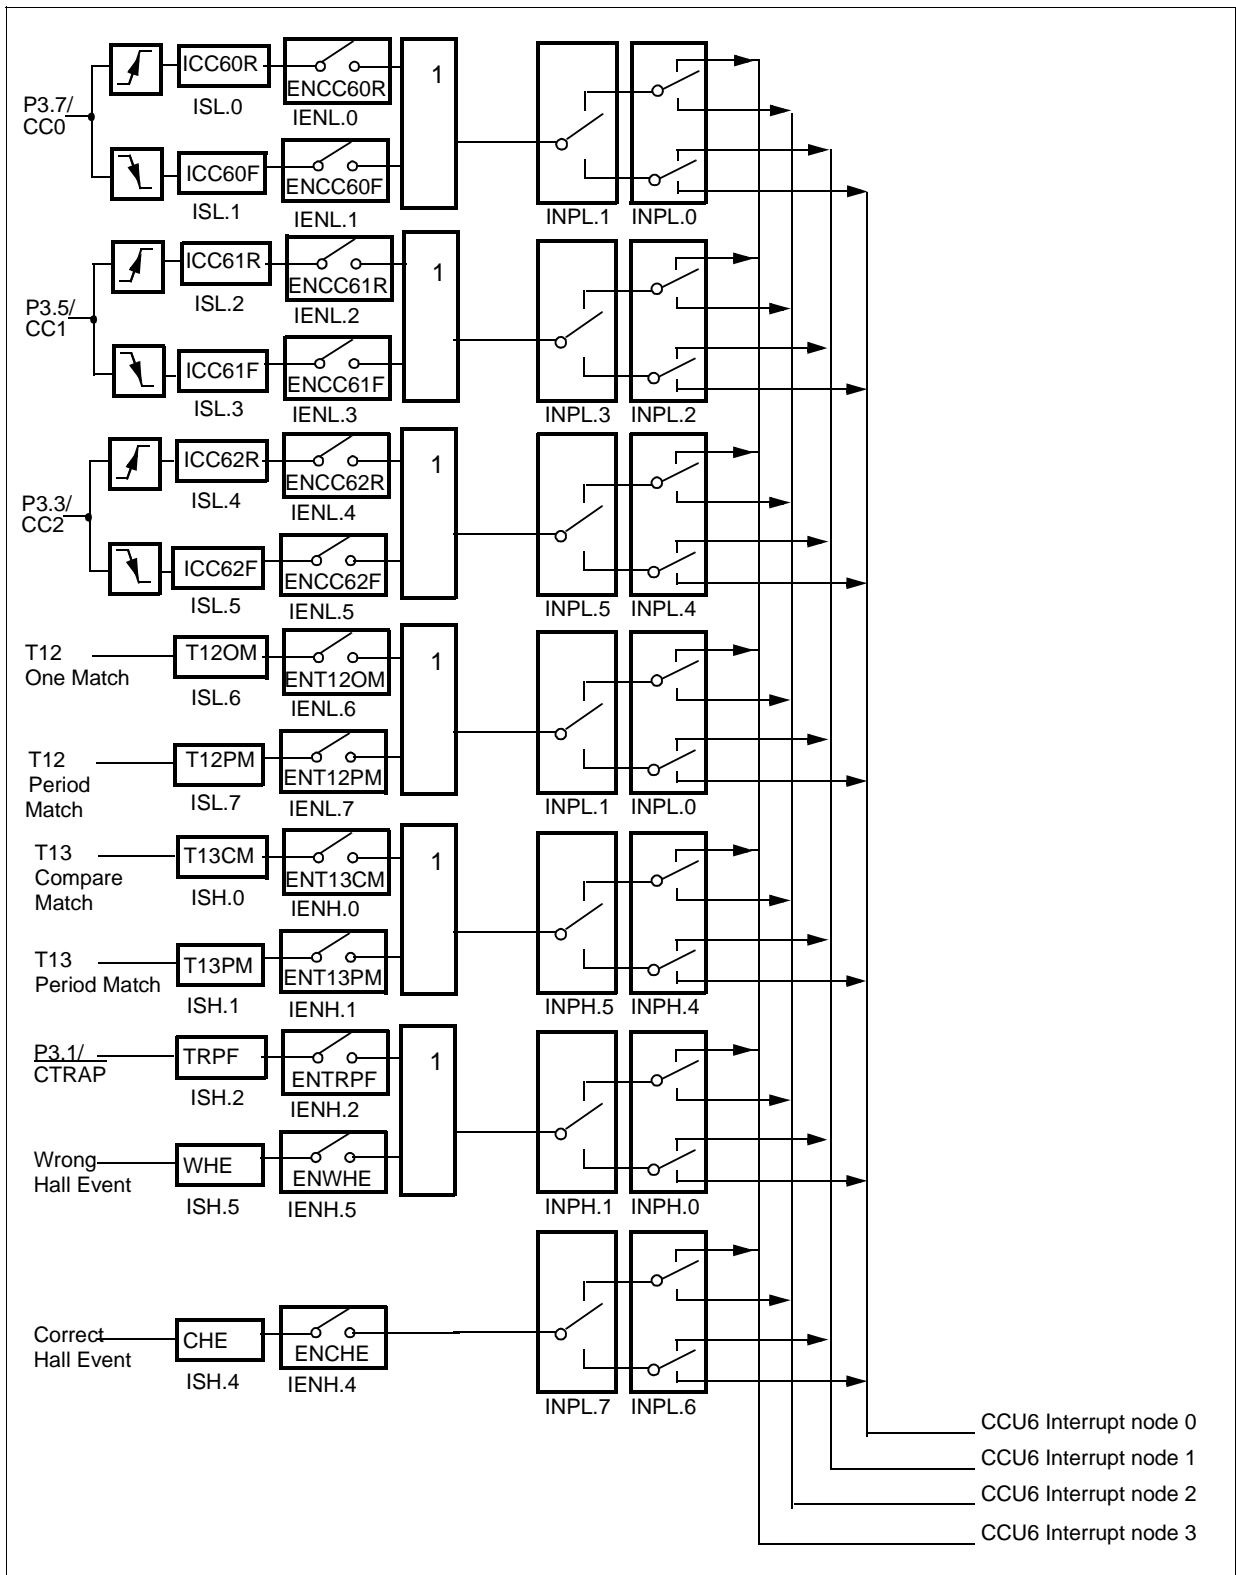

The C868 provides 13 interrupt vectors with two priority levels. Nine interrupt requests are generated by the on-chip peripherals (timer 0, timer 1, timer 2, serial channel, A/D converter, and the capture/compare unit with 4 interrupts) and four interrupts may be triggered externally.

The wake-up from power-down mode interrupt has a special functionality which allows the software power-down mode to be terminated by a short negative pulse at pins CCPOS0/T2/INT0/AN0 or P1.4/RxD.

The 13 interrupt sources are divided into six groups. Each group can be programmed to one of the two interrupt priority levels. Additionally, 4 of these interrupt sources are channeled from 7 Capture/Compare (CCU6) interrupt sources.

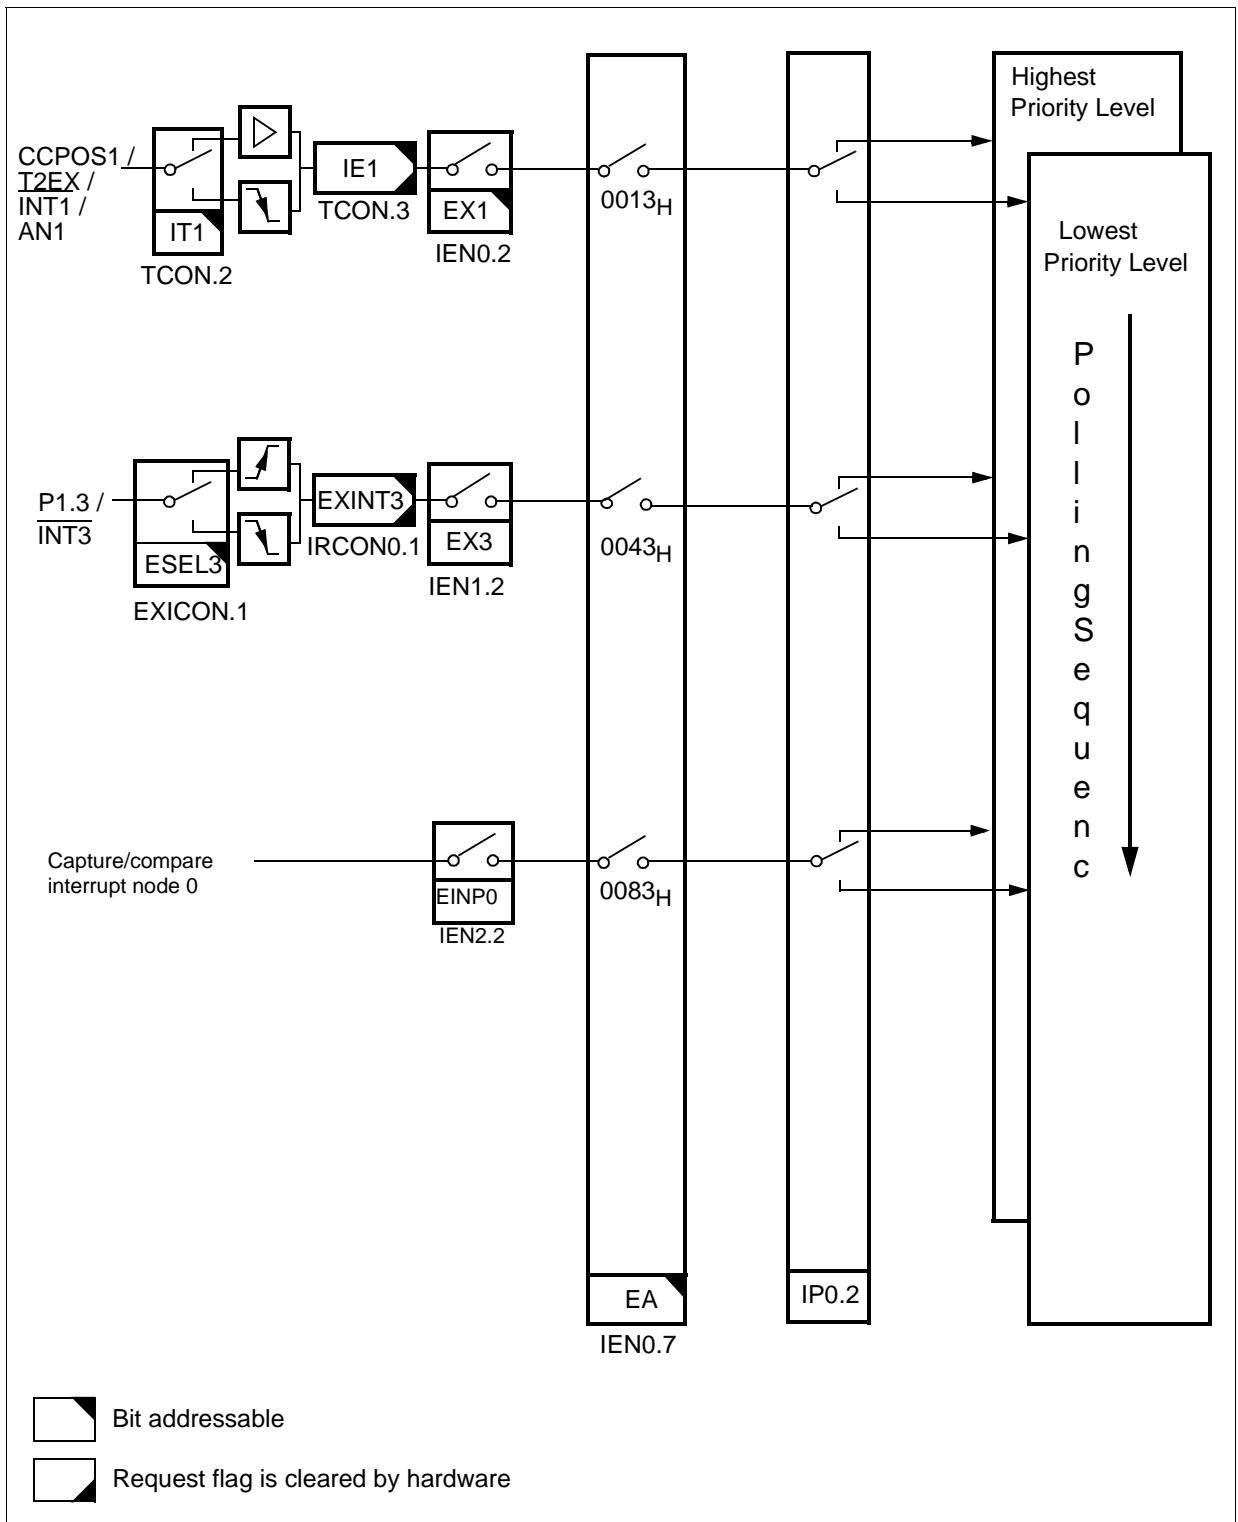

### 7.1 Structure of the Interrupt System

**Figure 7-1** to **Figure 7-6** give a general overview of the interrupt sources and illustrate the request and control flags which are described in the next sections.

**Figure 7-1** Capture/Compare module interrupt structure

## 7.2 Interrupt Registers

### 7.2.1 Interrupt Enable Registers

Each interrupt vector can be individually enabled or disabled by setting or clearing the corresponding bit in the interrupt enable registers IEN0, IEN1, IEN2. Register IEN0 also contains the global disable bit (EA), which can be cleared to disable all interrupts at once. Generally, after reset all interrupt enable bits are set to 0. That means that the corresponding interrupts are disabled.

The SFR IEN0 contains the enable bits for the external interrupts 0 and 1, the timer interrupts, and the UART interrupt.

## 7.2.2 Interrupt Request Flags

The request flags for the different interrupt sources are located in several special function registers. This section describes the locations and meanings of these interrupt request flags in detail.

### TCON

#### Timer 0/1 Control Register

[Reset value: 00<sub>H</sub>]

8F <sub>H</sub>	8E <sub>H</sub>	8D <sub>H</sub>	8C <sub>H</sub>	8B <sub>H</sub>	8A <sub>H</sub>	89 <sub>H</sub>	88 <sub>H</sub>
<b>TF1</b>	<b>TR1</b>	<b>TF0</b>	<b>TR0</b>	<b>IE1</b>	<b>IT1</b>	<b>IE0</b>	<b>IT0</b>
rwh	rw	rwh	rw	rwh	rw	rwh	rw

The functions of the shaded bits are not described here

Field	Bits	Typ	Description
<b>IT0</b>	0	rw	<b>External interrupt 0 level/edge trigger control flag</b> If IT0 = 0, low level triggered external interrupt 0 is selected. If IT0 = 1, falling edge triggered external interrupt 0 is selected.
<b>IE0</b>	1	rwh	<b>External interrupt 0 request flag</b> Set by hardware when external interrupt 0 edge is detected. Cleared by hardware when processor vectors to interrupt routine.
<b>IT1</b>	2	rw	<b>External interrupt 1 level/edge trigger control flag</b> If IT1 = 0, low level triggered external interrupt 1 is selected. If IT1 = 1, falling edge triggered external interrupt 1 is selected.
<b>IE1</b>	3	rwh	<b>External interrupt 1 request flag</b> Set by hardware when external interrupt 1 edge is detected. Cleared by hardware when processor vectors to interrupt routine.

Interrupt System

Field	Bits	Typ	Description
TF0	5	rwh	<b>Timer 0 overflow flag</b> Set by hardware on timer/counter 0 overflow. Cleared by hardware when processor vectors to interrupt routine.
TF1	7	rwh	<b>Timer 1 overflow flag</b> Set by hardware on timer/counter 1 overflow. Cleared by hardware when processor vectors to interrupt routine.

The **timer 0 and timer 1 interrupts** are generated by TF0 and TF1 in register TCON, which are set by a rollover in their respective timer/counter registers. When a timer interrupt is generated, the flag that generated it is cleared by the on-chip hardware when the service routine is vectored to.

The **external interrupts 0 and 1** (CCPOS0/T2/ $\overline{\text{INT0}}$ /AN0 , CCPOS1/T2EX/ $\overline{\text{INT1}}$ /AN1) can each be either level-activated or negative transition-activated, depending on bits IT0 and IT1 in register TCON. The flags that actually generate these interrupts are bits IE0 and IE1 in TCON. When an external interrupt is generated, the flag that generated this interrupt is cleared by the hardware when the service routine is vectored to, but only if the interrupt was transition-activated. If the interrupt was level-activated, then the requesting external source directly controls the request flag, rather than the on-chip hardware.

**IRCON0**

**External Interrupt Control Register 0**

[Reset value: XXXXXX00<sub>B</sub>]

7	6	5	4	3	2	1	0
-	-	-	-	-	-	<b>EXINT3</b>	<b>EXINT2</b>
r	r	r	r	r	r	rwh	rwh

Field	Bits	Typ	Description
EXINT2	0	rwh	<b>Interrupt Request Flag for External Interrupt 2</b> 0 : Interrupt request is not active, cleared by software. (default) 1 : Interrupt request is active, set by hardware.

Interrupt System

Field	Bits	Typ	Description
EXINT3	1	rwh	<b>Interrupt Request Flag for External Interrupt 3</b> 0 : Interrupt request is not active, cleared by software. (default) 1 : Interrupt request is active, set by hardware.
-	[7:2]	r	<b>reserved;</b> returns '0' if read; should be written with '0';

The external interrupt 2 and 3(CCPOS2/ $\overline{\text{INT2}}$ /AN2, P1.3/ $\overline{\text{INT3}}$ ) can be either positive or negative transition-activated, depending on the bits register EXICON. The flags that actually generates this interrupt are bits EXINT2 and EXINT3 in register IRCON0. When processing the external interrupts, flags must be cleared by software.

**EXICON**

**External Interrupt Control Register**

[Reset value: XXXXXX00<sub>B</sub>]

7	6	5	4	3	2	1	0
-	-	-	-	-	-	<b>ESEL3</b>	<b>ESEL2</b>
r	r	r	r	r	r	rw	rw

Field	Bits	Typ	Description
ESEL2	[7:0]	rw	<b>External Interrupt 2 Edge Trigger Select.</b> 0 : Interrupt on falling edge. (default) 1 : Interrupt on rising edge.
ESEL3	[7:0]	rw	<b>External Interrupt 3 Edge Trigger Select.</b> 0 : Interrupt on falling edge. (default) 1 : Interrupt on rising edge.
-	[7:2]	r	<b>reserved;</b> returns '0' if read; should be written with '0';

All external interrupts (CCPOS2/ $\overline{\text{INT2}}$ /AN2, P1.3/ $\overline{\text{INT3}}$ ) can be either positive or negative transition-activated, depending on the bits register EXICON. The flags that actually generates this interrupt are bits EXINT2 and EXINT3 in register IRCON0. The flags must be cleared by software.

**T2CON**

**Timer 2 Control Register**

[Reset value: 00<sub>H</sub>]

CF <sub>H</sub>	CE <sub>H</sub>	CD <sub>H</sub>	CC <sub>H</sub>	CB <sub>H</sub>	CA <sub>H</sub>	C9 <sub>H</sub>	C8 <sub>H</sub>
<b>TF2</b>	<b>EXF2</b>	<b>RCLK</b>	<b>TCLK</b>	<b>EXEN2</b>	<b>TR2</b>	<b>C/T2</b>	<b>CP/RL2</b>
rwh	rwh	rw	rw	rw	rw	rw	rw

The functions of the shaded bits are not described here

Field	Bits	Typ	Description
EXF2	6	rwh	<b>Timer/counter 2 External Flag</b> This bit is set by hardware when a capture/reload occurred upon a negative transition at pin T2EX, if bit EXEN2=1. An interrupt request to the core is generated, unless bit DCEN=1. This bit must be cleared by software.
TF2	7	rw	Timer 2 Overflow Flag Set by a timer 2 overflow. Must be cleared by software. TF2 will not be set when either RCLK=1 or TCLK=1.

The **timer 2 interrupt** is generated by bit TF2 or EXF2 in register T2CON. These flags are not cleared by hardware when the service routine is vectored to. They should be cleared by software.

**IRCON1**

**External Interrupt Request Register 1**

[Reset value: XXXXXXX0<sub>B</sub>]

7	6	5	4	3	2	1	0
-	-	-	-	-	-	-	<b>IADC</b>
r	r	r	r	r	r	r	rwh

Field	Bits	Typ	Description
<b>IADC</b>	0	rwh	<b>Interrupt Request Flag for ADC</b> 0 : Interrupt request is not active, cleared by software. (default) 1 : Interrupt request is active, set by hardware.
-	[7:1]	r	<b>reserved;</b> returns '0' if read; should be written with '0';

The **A/D converter interrupt** is generated by IADC bit in register IRCON1. If an interrupt is generated, in any case the converted result in ADDATH is valid on the first instruction of the interrupt service routine. If continuous conversion is established, IADC is set once during each conversion. If an A/D converter interrupt is generated, flag IADC will have to be cleared by software.

**SCON**  
**Serial Channel Control Register**

[Reset value: 00<sub>H</sub>]

9F <sub>H</sub>	9E <sub>H</sub>	9D <sub>H</sub>	9C <sub>H</sub>	9B <sub>H</sub>	9A <sub>H</sub>	99 <sub>H</sub>	98 <sub>H</sub>
<b>SM0</b>	<b>SM1</b>	<b>SM2</b>	<b>REN</b>	<b>TB8</b>	<b>RB8</b>	<b>TI</b>	<b>RI</b>
rwh	rwh	rw	rw	rw	rw	rwh	rwh

The functions of the shaded bits are not described here

Field	Bits	Typ	Description
<b>RI</b>	0	rwh	<b>Serial interface receiver interrupt flag</b> Set by hardware if a serial data byte has been received. Must be cleared by software.
<b>TI</b>	1	rwh	<b>Serial interface transmitter interrupt flag</b> Set by hardware at the end of a serial data transmission. Must be cleared by software.

The **serial interface interrupt** is generated by a logical OR of flag RI and TI in SFR SCON. Neither of these flags is cleared by hardware when the service routine is vectored to. In fact, the service routine will normally have to determine whether it was the receive interrupt flag or the transmission interrupt flag that generated the interrupt, and the corresponding bit will have to be cleared by software.

### 7.2.3 Interrupt Control Registers for CCU6

Register IS contains the individual interrupt request bits. This register can only be read, write actions have no impact on the contents of this register. The SW can set or reset the bits individually by writing to the registers ISS (to set the bits) or to register ISR (to reset the bits).

#### ISL

TRPF	2	rh	<p><b>Trap Flag</b></p> <p>The trap flag TRPF will be set by HW if TRPPEN='1' and CTRAP='0' or by SW. If TRPM2='0', bit TRPF is reset by HW if the input <u>CTRAP</u> becomes inactive (TRPPEN='1'). If TRPM2='1', bit TRPF has to be reset by SW in order to leave the trap state.</p> <p>0 The trap condition has not been detected.</p> <p>1 The trap condition has been detected (input <u>CTRAP</u> has been '0' or by SW).</p>
TRPS <sup>1)</sup>	3	rh	<p><b>Trap State</b></p> <p>0 The trap state is not active.</p> <p>1 The trap state is active. Bit TRPS is set while bit TRPF='1'. It is reset according to the mode selected in register TRPCTR.</p>

**Interrupt System**

Field	Bits	Type	Description
<b>CHE<sup>2)</sup></b>	4	rh	<b>Correct Hall Event</b> 0 A transition to a correct (=expected) hall event has not yet been detected since this bit has been reset for the last time. 1 A transition to a correct (=expected) hall event has not yet been detected.
<b>WHE<sup>3)</sup></b>	5	rh	<b>Wrong Hall Event</b> 0 A transition to a wrong hall event (not the expected one) has not yet been detected since this bit has been reset for the last time. 1 A transition to a wrong hall event (not the expected one) has been detected.
<b>IDLE<sup>4)</sup></b>	6	rh	<b>IDLE State</b> This bit is set together with bit WHE (wrong hall event) and it has to be reset by SW. 0 No action. 1 Bitfield MCMP is cleared, the selected outputs are set to passive state.
-	7	r	<b>reserved;</b> returns '0' if read; should be written with '0';

- 1) During the trap state, the selected outputs are set to the passive state. The logic level driven during the passive state is defined by the corresponding bit in register CCMCON. Bit TRPS='1' and TRPF='0' can occur if the trap condition is no longer active but the selected synchronization has not yet taken place.
- 2) On every valid hall edge the contents of CURH is compared with the pattern on pin CCPOSx and if equal bit CHE is set.
- 3) On every valid hall edge the contents of EXPH is compared with the pattern on pin CCPOSx. If both compares (CURH and EXPH with CCPOSx) are not true, bit WHE (wrong hall event) is set.
- 4) Bit field MCMP is hold to '0' by hardware as long as IDLE = '1'.

*Note: Not all bits in register IS can generate an interrupt. Other status bits have been added, which have a similar structure for their set and reset actions.*

*Note: The interrupt generation is independent from the value of the bits in register IS, e.g. the interrupt will be generated (if enabled) even if the corresponding bit is already set. The trigger for an interrupt generation is the detection of a set condition (by HW or SW) for the corresponding bit in register IS.*

*Note: In compare mode (and hall mode), the timer-related interrupts are only generated while the timer is running (TxR=1). In capture mode, the capture interrupts are also generated while the timer T12 is stopped.*

**Interrupt System**

Register ISS contains the individual interrupt request set bits to generate a CCU6 interrupt request by software.

### 7.2.4 Interrupt Priority Registers

The lower six bits of these two registers are used to define the interrupt priority level of the interrupt groups as they are defined in [Table 7-2](#) in the next section.

#### IP0

#### Interrupt Priority Register 0

[Reset value: XX000000<sub>B</sub>]

Field	Bits	Typ	Description
<b>IP0x</b> x=0..5	[5..0]	rw	<b>Interrupt group priority level bits</b> 0 Interrupt group x is set to priority level 0 (lowest) 1 Interrupt group x is set to priority level 1 (highest)
-	[7:6]	r	<b>reserved;</b> returns '0' if read; should be written with '0';

### 7.3 Interrupt Priority Level Structure

The 13 interrupt sources of the C868 are grouped according to the listing in [Table 7-1](#).

**Table 7-1 Interrupt Source Structure**

Interrupt Group	Associated Interrupts		
0	External interrupt 0	A/D converter interrupt	
1	Timer 0 Overflow	External interrupt 2	
2	External interrupt 1	External interrupt 3	Capture/compare interrupt node 0
3	Timer 1 overflow	Capture/compare interrupt node 1	
4	Capture/compare interrupt node 2	Serial interrupt	
5	Timer 2 overflow	Capture/compare interrupt node 3	

Each group of interrupt sources can be programmed individually to one of two priority levels by setting or clearing one bit in the special function register IP0. A low-priority interrupt can be interrupted by a high-priority interrupt, but not by another interrupt of the same or a lower priority. An interrupt of the highest priority level cannot be interrupted by another interrupt source.

If two or more requests of different priority levels are received simultaneously, the request of the highest priority is serviced first. If requests of the same priority level are received simultaneously, an internal polling sequence determines which request is to be serviced first. Thus, within each priority level there is a second priority structure determined by the polling sequence. This is illustrated in [Table 7-2](#).

**Table 7-2 Interrupt Source Structure**

Interrupt Group	Priority Bits of Interrupt Group	Interrupt Source Priority				Priority
		High Priority	→		Low	
0	IP0.0	EXINT0	IADC			High ↓ Low
1	IP0.1	TF0	EXINT2			
2	IP0.2	EXINT1	EXINT3	INP0 <sup>1)</sup>		
3	IP0.3	TF1	INP1 <sup>1)</sup>			
4	IP0.4	RI + TI	INP2 <sup>1)</sup>			
5	IP0.5	TF2	INP3 <sup>1)</sup>			

<sup>1)</sup> Capture/compare has 10 interrupt sources channeled to the 4 interrupt nodes INP0..3. The 3 capture/compare ports has 3 pairs of interrupt request flags, ICC60R, ICC60F, ICC61R, ICC61F, ICC62R, ICC62F. The other flags are T12OM, T12PM, T13CM, T13PM, TRPF, WHE, CHE.

Within a column, the topmost interrupt is serviced first, then the second and the third, when available. The interrupt groups are serviced from left to right of the table. A low-priority interrupt can itself be interrupted by a higher-priority interrupt, but not by another interrupt of the same or a lower priority. An interrupt of the highest priority level cannot be interrupted by another interrupt source.

If two or more requests of different priority levels are received simultaneously, the request of the highest priority is serviced first. If requests of the same priority level are received simultaneously, an internal polling sequence determines which request is to be serviced first. Thus, within each priority level there is a second priority structure which is illustrated in table 7-10.

The “priority-within-level” structure is only used to resolve simultaneous requests of the same priority level.

### 7.4 How Interrupts are Handled

The interrupt flags are sampled at S5P2 in each machine cycle. The sampled flags are polled during the following machine cycle. If one of the flags was in a set condition at S5P2 of the preceding cycle, the polling cycle will find it and the interrupt system will generate a LCALL to the appropriate service routine, provided this hardware-generated LCALL is not blocked by any of the following conditions:

An interrupt of equal or higher priority is already in progress.

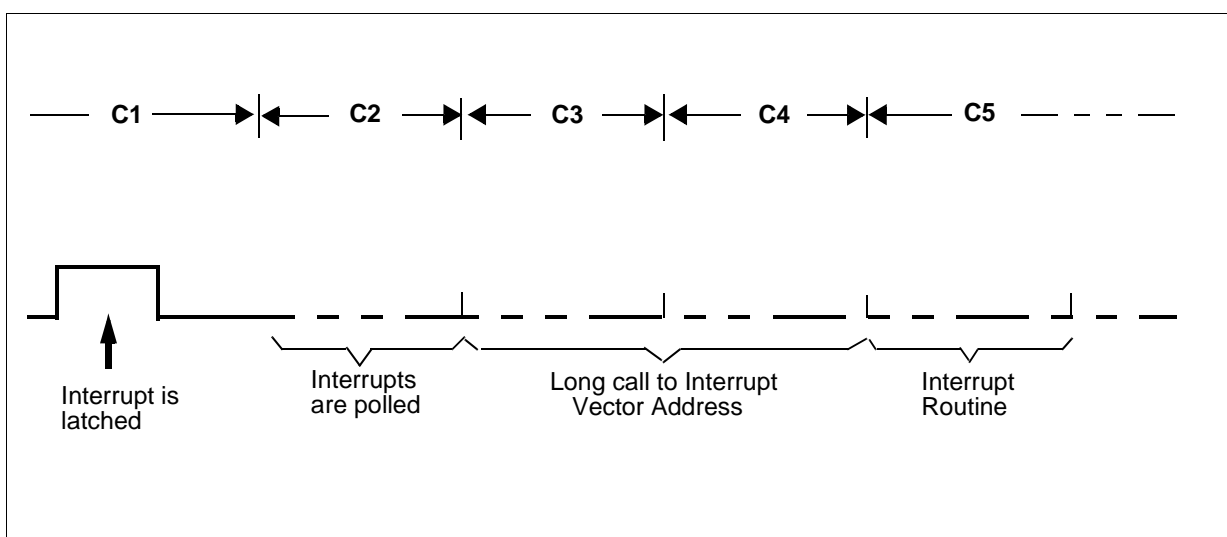

The current (polling) cycle is not in the final cycle of the instruction in progress.

The instruction in progress is RETI or any write access to registers IEN0/IEN1 or IP0.

Any of these three conditions will block the generation of the LCALL to the interrupt service routine. Condition 2 ensures that the instruction in progress is completed before vectoring to any service routine. Condition 3 ensures that if the instruction in progress is RETI or any write access to registers IEN0/IEN1 or IP0, then at least one more instruction will be executed before any interrupt is vectored to; this delay guarantees that changes of the interrupt status can be observed by the CPU.

The polling cycle is repeated with each machine cycle, and the values polled are the values that were present at S5P2 of the previous machine cycle. Note that if any interrupt flag is active but not being responded to for one of the conditions already mentioned, or if the flag is no longer active when the blocking condition is removed, the denied interrupt will not be serviced. In other words, the fact that the interrupt flag was once active but not serviced is not remembered. Every polling cycle interrogates only the pending interrupt requests.

The polling cycle/LCALL sequence is illustrated in [Table 7-7](#).

**Figure 7-7 Interrupt Response Timing Diagram**

**Interrupt System**

Note that if an interrupt of a higher priority level goes active prior to S5P2 in the machine cycle labeled C3 in [Figure 7-7](#) then, in accordance with the above rules, it will be vectored to during C5 and C6 without any instruction for the lower priority routine to be executed.

Thus, the processor acknowledges an interrupt request by executing a hardware-generated LCALL to the appropriate servicing routine. In some cases it also clears the flag that generated the interrupt, while in other cases it does not; then this has to be done by the user's software. The hardware clears the external interrupt flags IE0 and IE1 only if they were transition-activated. The hardware-generated LCALL pushes the contents of the program counter onto the stack (but it does not save the PSW) and reloads the program counter with an address that depends on the source of the interrupt being vectored to, as shown in the following [Table 7-3](#).

**Table 7-3 Interrupt Source and Vectors**

Interrupt Source	Interrupt Vector Address(core connections)	Interrupt Request Flags

1) Capture/compare has 10 interrupt sources channeled to the 4 interrupt nodes INP0..3. The 3 capture/compare ports has 3 pairs of interrupt request flags, ICC60R, ICC60F, ICC61R, ICC61F, ICC62R, ICC62F. The other flags are T12OM, T12PM, T13CM, T13PM, TRPF, WHE, CHE.

Execution proceeds from that location until the RETI instruction is encountered. The RETI instruction informs the processor that the interrupt routine is no longer in progress, then pops the two top bytes from the stack and reloads the program counter. Execution of the interrupted program continues from the point where it was stopped. Note that the RETI instruction is very important because it informs the processor that the program left the current interrupt priority level. A simple RET instruction would also have returned execution to the interrupted program, but it would have left the interrupt control system thinking an interrupt was still in progress. In this case no interrupt of the same or lower priority level would be acknowledged.

### External Interrupts

The external interrupts 0 and 1 can be programmed to be level-activated or negative-transition activated by setting or clearing bit IT<sub>x</sub> (x = 0 or 1), respectively in register TCON. If IT<sub>x</sub> = 0, external interrupt x is triggered by a detected low level at the  $\overline{\text{INTx}}$  pin. If IT<sub>x</sub> = 1, external interrupt x is negative edge-triggered. In this mode, if successive samples of the  $\overline{\text{INTx}}$  pin show a high in one cycle and a low in the next cycle, interrupt request flag IEx in TCON is set. Flag bit IEx=1 then requests the interrupt.

If the external interrupt 0 or 1 is level-activated, the external source has to hold the request active until the requested interrupt is actually generated. Then it has to deactivate the request before the interrupt service routine is completed, or else another interrupt will be generated.

The external interrupts 2 and 3 can be programmed to be negative or positive transition-activated by setting or clearing bits I2FR or I3FR in register T2CON. If I<sub>x</sub>FR = 0 (x = 2 or 3) then the external interrupt x is negative transition-activated. If I<sub>x</sub>FR = 1, external interrupt is triggered by a positive transition.

Since the external interrupt pins are sampled once in each machine cycle, an input high or low should be held for at least 3 oscillator periods to ensure sampling. If the external interrupt is positive (negative) transition-activated, the external source has to hold the request pin low (high) for at least one cycle, and then hold it high (low) for at least one

cycle to ensure that the transition is recognized so that the corresponding interrupt request flag will be set (see [Figure 7-8](#)). The external interrupt request flags will automatically be cleared by the CPU when the service routine is called.

**Figure 7-8 External Interrupt Detection**

## 7.5 Interrupt Response Time

If an external interrupt is recognized, its corresponding request flag is set at S5P2 in every machine cycle. The value is not polled by the circuitry until the next machine cycle. If the request is active and conditions are right for it to be acknowledged, a hardware subroutine call to the requested service routine will be the next instruction to be executed. The call itself takes two cycles. Thus a minimum of three complete machine cycles will elapse between activation and external interrupt request and the beginning of execution of the first instruction of the service routine.

A longer response time would be obtained if the request was blocked by one of the three previously listed conditions. If an interrupt of equal or higher priority is already in progress, the additional wait time obviously depends on the nature of the other interrupt's service routine. If the instruction in progress is not in its final cycle, the additional wait time cannot be more than 3 cycles since the longest instructions (MUL and DIV) are only 4 cycles long; and, if the instruction in progress is RETI or a write access to registers IEN0, IEN1 or IPO the additional wait time cannot be more than 5 cycles (a maximum of one more

---

**Interrupt System**

cycle to complete the instruction in progress, plus 4 cycles to complete the next instruction, if the instruction is MUL or DIV).

Thus a single interrupt system, the response time is always more than 3 cycles and less than 9 cycles.

## 8 Power Saving Modes

The C868 provides two basic power saving modes, the idle mode and the power down mode. Additionally, a slow down mode is available. This power saving mode reduces the internal clock rate in normal operating mode and it can also be used for further power reduction in idle mode. Further power saving is possible in the normal, idle and slow down modes by disabling unutilized peripherals. The peripherals that has the power-down capability are the timer/counter2, capture/compare unit and the A/D converter.

### 8.1 Power Saving Mode Control Registers

The functions of the power saving modes are controlled by bits which are located in the special function registers PCON and PMCON0.

The bits PDE and IDLE located in SFR PCON select the power down mode or the idle mode, respectively. If the power down mode and the idle mode are set at the same time, power down mode takes precedence. Furthermore, register PCON contains two general purpose flags. For example, the flag bits GF0 and GF1 can be used to give an indication if an interrupt occurred during normal operation or during idle mode. For this, an instruction that activates idle mode can also set one or both flag bits. When idle mode is terminated by an interrupt, the interrupt service routine can examine the flag bits.

## 8.2 Register Description

<b>WS</b>	1	rw	<b>Wake Up Source Select.</b> This is applicable only if EWPD is set. 0 : $\overline{INT0}$ will terminate power down mode. (default) 1 : RXD will terminate power down mode.
<b>SDSTAT</b>	2	rh	<b>Slow Down Status Bit.</b> 0 : Slow Down Mode is not active, ie system clock is not slow down clock. 1 : Slow Down Mode is active, ie system clock is the slow down clock. This bit is set or cleared by hardware only.
-	[7:5]	r	<b>reserved;</b> returns '0' if read; should be written with '0';

### 8.3 Idle Mode

In the idle mode the oscillator of the C868 continues to run, but the CPU is gated off from the clock signal. However, the interrupt system, the serial port, the A/D converter, the capture/compare unit, and all timers with the exception of the watchdog timer are further provided with the clock. The CPU status is preserved in its entirety: the stack pointer, program counter, program status word, accumulator, and all other registers maintain their data during idle mode.

The reduction of power consumption, which can be achieved by this feature depends on the number of peripherals running. If all timers are stopped and the A/D converter, and the serial interfaces are not running, the maximum power reduction can be achieved. This state is also the test condition for the idle mode  $I_{DDC}$ .

Thus, the user has to take care which peripheral should continue to run and which has to be stopped during idle mode. Also the state of all port pins – either the pins controlled by their latches or controlled by their secondary functions – depends on the status of the controller when entering idle mode.

Normally, the port pins hold the logical state they had at the time when the idle mode was activated. If some pins are programmed to serve as alternate functions they still continue to output during idle mode if the assigned function is on. This especially applies to the serial interface in case it cannot finish reception or transmission during normal operation.

As in normal operation mode, the ports can be used as inputs during idle mode. Thus a capture or reload operation can be triggered, the timers can be used to count external events, and external interrupts will be detected.

The idle mode is a useful feature which makes it possible to "freeze" the processor's status - either for a predefined time, or until an external event reverts the controller to normal operation, as discussed below. The watchdog timer is the only peripheral which is automatically stopped during idle mode.

The idle mode is entered by setting the flag bit IDLE (PCON.0).

There are two ways to terminate the idle mode:

The idle mode can be terminated by activating any enabled interrupt. The CPU operation is resumed, the interrupt will be serviced and the next instruction to be executed after the RETI instruction will be the one following the instruction that had set the bit IDLE.

The other way to terminate the idle mode, is a hardware reset.

## 8.4 Slow Down Mode Operation

In some applications, where power consumption and dissipation are critical, the controller might run for a certain time at reduced speed (e.g. if the controller is waiting for an input signal). Since in CMOS devices there is an almost linear dependence of the operating frequency and the power supply current, a reduction of the operating frequency results in reduced power consumption.

The slow down mode is activated by setting the bit SD in SFR PCON. If the slow down mode is enabled, the clock signals for the CPU and the peripheral units can be reduced from 1/2 to 1/32 of the nominal system clock rate. The clock divider is described in the Reset and System Clock Operation chapter. The controller actually enters the slow down mode after a short synchronization period (max. two machine cycles). The slow down mode is terminated by clearing bit SD.

The slow down mode can be combined with the idle mode by setting the IDLE and SD bits in SFR PCON.

There are two ways to terminate the combined Idle and Slow Down Mode :

- The idle mode can be terminated by activation of any enabled interrupt. The CPU operation is resumed, the interrupt will be serviced and the next instruction to be executed after the RETI instruction will be the one following the instruction that had set the bits IDLE and SD. Nevertheless the slow down mode keeps enabled and if required has to be terminated by clearing the bit SD in the corresponding interrupt service routine or at any point in the program where the user no longer requires the slow-down mode power saving.
- The other possibility of terminating the combined idle and slow down mode is a hardware reset.

## 8.5 Software Power Down Mode

In the software power down mode, the on-chip oscillator which operates with the XTAL pins and the PLL are all stopped. Therefore, all functions of the microcontroller are stopped and only the contents of the on-chip RAM, XRAM and the SFR's are maintained. The port pins, which are controlled by their port latches, output the values that are held by their SFR's. The port pins which serve the alternate output functions show the values they had at the end of the last cycle of the instruction which initiated the power down mode. ALE is held at logic level high unless it is disabled.

In the power down mode of operation,  $V_{DDC}$  and  $V_{DDP}$  can be reduced to minimize power consumption. It must be ensured, however, that  $V_{DDC}$  and  $V_{DDP}$  is not reduced before the power down mode is invoked, and that  $V_{DDC}$  and  $V_{DDP}$  is restored to its normal operating level before the power down mode is terminated. However,  $V_{DDC}$  cannot be lower than  $V_{DDP}$  by more than 1(tbd) volt.

The software power down mode can be left either by an active reset signal or by a low signal at one of the wake-up source pins. Using reset to leave power down mode puts the microcontroller with its SFRs into the reset state. Using either the  $\overline{INT0}$  pin or the RXD pin for power down mode exit starts the on-chip oscillator and the PLL and maintains the state of the SFRs, which have been frozen when power down mode is entered. Leaving power down mode should not be done before  $V_{DDC}$  and  $V_{DDP}$  is restored to its nominal operating level.

The software power down mode is entered by setting bit PDE (PCON.1).

*Note: Before entering the power down mode, an A/D conversion in progress must be stopped.*

### 8.5.1 Exit from Software Power Down Mode

If power down mode is exit via a hardware reset, the microcontroller with its SFRs is put into the hardware reset state and the content of RAM and XRAM are not changed. The reset signal that terminates the power down mode also restarts the on-chip oscillator and the PLL. The reset operation should not be activated before  $V_{DDC}$  and  $V_{DDP}$  is restored to its normal operating level.

**Figure 8-1** shows the behaviour when power down mode is left via the  $\overline{INT0}$  or the RXD wake-up capability.

**Figure 8-1 Wake-up from Power Down Mode Procedure**

When the power down mode wake-up capability has been enabled (bit EWPD in SFR PMCON0 set) prior to entering power down mode and bit WS in SFR PMCON0 is cleared, the power down mode can be exit via  $\overline{\text{INT0}}$  while executing the following procedure :

1. In power down mode pin  $\overline{\text{INT0}}$  must be held at high level.
2. Power down mode is left when  $\overline{\text{INT0}}$  goes low (latch phase). After this delay the on-chip oscillator and the PLL are started, the state of pin  $\overline{\text{INT0}}$  is internally latched, and  $\overline{\text{INT0}}$  can be set again to high level if required.
3. The on-chip oscillator takes about, typically, 10 ms to stabilize.
4. The PLL will be locked within 1 ms after the on-chip oscillator clock is detected for stable nominal frequency. Subsequently, the microcontroller starts again with its operation initiating the power down wake-up interrupt. The interrupt address of the first instruction to be executed after wake-up is  $007B_H$ . Instruction fetches during the interrupt call are, however, discarded.
5. After the RETI instruction of the power down wake-up interrupt routine has been executed, the instruction which follows the initiating power down mode instruction sequence will be executed.

All interrupts of the C868 are disabled from phase 2 until the end of phase 5. Other Interrupts can be first handled after the RETI instruction of the wake-up interrupt routine.

The procedure to exit the software power down mode via the  $\overline{\text{RXD}}$  pin is identical to the above procedure except that in this case pin  $\overline{\text{RXD}}$  replaces pin  $\overline{\text{INT0}}$ , and bit WS in SFR PCON1 should be set prior to entering software power down mode.

## Infineon goes for Business Excellence

“Business excellence means intelligent approaches and clearly defined processes, which are both constantly under review and ultimately lead to good operating results.

Better operating results and business excellence mean less idleness and wastefulness for all of us, more professional success, more accurate information, a better overview and, thereby, less frustration and more satisfaction.”

Dr. Ulrich Schumacher
